# High Performance ECL Data ECLinPS and ECLinPS Lite 

## DATA SHEET CLASSIFICATIONS

## Product Preview

This heading on a data sheet indicates that the device is in the formative stages or in design (under development). The disclaimer at the bottom of the first page reads: "This document contains information on a product under development. Motorola reserves the right to change or discontinue this product without notice."

## Advance Information

This heading on a data sheet indicates that the device is in sampling, pre-production, or first production stages. The disclaimer at the bottom of the first page reads: "This document contains information on a new product. Specifications and information herein are subject to change without notice."

## Fully Released

A fully released data sheet contains neither a classification heading nor a disclaimer at the bottom of the first page. This document contains information on a product in full production. Guaranteed limits will not be changed without written notice to your Motorola Semiconductor Sales Office.

The data sheets contained in this book were the most current available as of the date of publication, July 1996.

A more current version of data sheets designated Product Preview or Advance Information may be available.

## High Performance ECL Data ECLinPS and ECLinPS Lite

## This databook contains device specifications for Motorola's advanced ECL logic families, ECLinPS and

 ECLinPS Lite.ECLinPS* (ECL in picoseconds) was developed in response to the need for an even higher performance ECL family of standard logic functions, particularly in the Computer, Automated Test, Instrumentation and Communications industries. Family general features as well as specific functions were developed in close consultation with ECL systems design engineers.
ECLinPS offers the user a single gate delay of 500ps max., including package delay, and a flip-flop toggle frequency of 1100 MHz .

ECLinPS is compatible with two different ECL standards. Each function is available with either MECL 10H compatibility (MC10Exxx series) or 100K compatibility (MC100Exxx series).

ECLinPS Lite is Motorola's family of single, essential logic primitives, (gates, muxes, flops etc.) along with translators, low voltage ECL logic devices and PLL support products.

ECLinPS is offered in the 28-lead plastic leaded chip carrier (PLCC), a J-lead surface mount IC package. ECLinPS Lite is offered in either 8, 16 or 20-lead industry standard SOIC packaging. These packages were selected for high performance, reduced parasitics and good thermal handling in low cost, standard packages, and reflect the industry trend towards surface mount assembly.

* Any reference to ECLinPS in the General Information or Applications Information sections of this book, unless otherwise noted, will include the ECLinPS Lite and Low Voltage ECLinPS families.

Motorola reserves the right to make changes without further notice to any products herein. Motorola makes no warranty, representation or guarantee regarding the suitability of its products for any particular purpose, nor does Motorola assume any liability arising out of the application or use of any product or circuit, and specifically disclaims any and all liability, including without limitation consequential or incidental damages. "Typical" parameters which may be provided in Motorola data sheets and/or specifications can and do vary in different applications and actual performance may vary over time. All operating parameters, including "Typicals" must be validated for each customer application by customer's technical experts. Motorola does not convey any license under its patent rights nor the rights of others. Motorola products are not designed, intended, or authorized for use as components in systems intended for surgical implant into the body, or other applications intended to support or sustain life, or for any other application in which the failure of the Motorola product could create a situation where personal injury or death may occur. Should Buyer purchase or use Motorola products for any such unintended or unauthorized application, Buyer shall indemnify and hold Motorola and its officers, employees, subsidiaries, affiliates, and distributors harmless against all claims, costs, damages, and expenses, and reasonable attorney fees arising out of, directly or indirectly, any claim of personal injury or death associated with such unintended or unauthorized use, even if such claim alleges that Motorola was negligent regarding the design or manufacture of the part. This section contains a numerical listing of ECLinPS and ECLinPS Lite family functions, a technical overview of the ECLinPS amd ECLinPS Lite families and an outline of their electrical characteristics. In addition, this section outlines the procedures and philosophies used to AC test the families. (MC10E/EL series devices are compatible with the MECL 10H family. MC100E/EL series are compatible with 100K ECL.)

# SECTION 4 <br> Family Overview 

## Introduction

Advances in bipolar processes led to a proliferation of very high speed LSI and VLSI gate arrays in high end computer applications. The advent of these high speed arrays created a need for a high speed logic family to tie or "glue" them together. Because arrays have a finite amount of circuitry and I/O pins, glue functions which are sensitive to either of these parameters may be better performed off of the array. In addition glue functions which require very tight skew control may be difficult to perform on an array due to the inherent skew of the large packages associated with large gate arrays. Therefore although the trend is to push more and more of the logic onto the array, there are design constraints which make performing some of the logic, such as clock distribution, multiplexing, decoding, latching, memory addressing and translating, in glue an attractive alternative.
The high end computer segment is not the only market segment pushing for higher performance logic parts. ATE, instrumentation and communication designs can have data rate requirements ranging from 300 MHz to as high as 2.5 GHz . Because large high speed arrays do not always lend themselves to passing high frequency signals on and off chip, portions of the designs must be realized with discrete logic. The current bipolar logic families are not capable of operating at these high frequencies.
To answer the call for a very high speed bipolar logic family Motorola designed and produced the ECLinPS* (ECL in Pico Seconds) logic family. The family is designed to meet the most stringent of system requirements in speed, skew and board density as well as maintaining compatibility to existing ECL families.

## ECL Design Benefits

The speed benefits of an ECL design over those of alternative logic technologies are well documented, however there are a number of other important features that make ECL an attractive technology for system designs. The ECLinPS logic family, as with other ECL families, affords the following advantages:

## Complimentary Outputs

Complimentary outputs are available on many functions with equal propagation delays between the two paths. This alleviates the need for external inverters and saves system power and board space while maintaining exceptional system timing.

## Transmission Line Drive Capability

The low output impedance, high input impedance and high current drive capability of ECL makes it an ideal technology for driving transmission lines. Regardless of the technology, as system speeds increase, interconnect becomes more of a transmission line phenomenon. With ECL no special line driving devices are necessary, as all ECL devices are line drivers.

## Constant Power Supply Current Drain

Because of the differential amplifier design used for ECL circuits, the current is not switched on and off but rather simply steered between two paths. Thus the current drain of an ECL device is independent of the logic state and the frequency of operation. This current stability greatly simplifies system power supply design.

## Input Pulldown Resistors

ECL inputs have $50 \mathrm{~K} \Omega-75 \mathrm{~K} \Omega$ internal pulldown resistors which pull the input to $\mathrm{V}_{\mathrm{EE}}$ (logic LOW) when left open. This allows unused inputs to be left open and greatly simplifies logic design.

## Differential Drive Capability

Because of the presence of high current drive complimentary outputs, ECL circuits are ideally suited for driving twisted pair lines or cables over long distances. With common mode noise rejection of 1 V or more, ECL line receivers are less susceptible to common mode noise. In addition, their differential inputs need only a few hundred millivolt voltage differences to correctly interpret the logic.

## High Speed Design Philosophy

Today a truly high speed logic family needs more than simply short propagation delays. The minimization of all types of skew, as well as a level of logic density which affords a smaller amount of board space for an equivalent function, are also necessities of a high speed family. The following summary will outline the steps taken by Motorola to achieve these goals in the development of the ECLinPS logic family.

## Fast Propagation Delays

The ECLinPS family boasts 500ps maximum packaged gate delays and typical flip-flop toggle frequencies of 1.4 GHz . Simple gate functions show typical propagation delays of 360 ps at 25 mW of power for a speed power product of only $9 p J$. For higher density devices internal gates run at 100ps with 5 mW of power for a speed power product of only 0.5 pJ .

## * Any reference to ECLinPS in this section includes the ECLinPS Lite and Low Voltage ECLinPS families.

## Internal Differential Interconnect

The propagation delay window size, skew between rising and falling inputs and susceptibility to noise are all phenomenon which are exacerbated by $V_{B B}$ switching reference variation. By extensively using differential interconnects internal to the chip, the ECLinPS family has been able to achieve superior performance in these areas.

## Propagation Delay Temperature Insensitivity

The variation of propagation delay through an ECLinPS device across temperature is typically less than 50ps. This stability allows for faster designs due to tighter delay windows across temperature.

## Input Impedance and Loading Capacitance

The input structures of the ECLinPS family show a positive real impedance across the applicable input frequency range. This ensures that the system will remain stable and operate as designed over a wide range of input frequencies. The input loading capacitance typically measures only 1.5 pF and is virtually independent of input fanout as the device capacitance is less than $5 \%$ of the total. Because the propagation delay of a signal down a transmission line is adversely affected by loading capacitance, the overall system speed is enhanced.

## Input Buffers

To minimize propagation delays in a system environment, inputs with a large internal fanout are buffered to minimize the loading capacitance on the transmission line.

## High Level of Integration

28-pin designs allow for the design of 9-bit functions for implementation in byte plus parity applications. Full byte plus parity implementation reduces total package count and saves expensive board space.

## Space Efficient Package

Surface mount PLCC package affords a high level of integration with a minimum amount of required board space. Quad layout of the package equalizes pin lengths thus minimizing the skew between similar internal paths.

## Flow Through Pin Assignment

Input and output pins have been laid out in a flow through pattern with the inputs on one side of the package and the outputs on the other. This flow through pattern helps to simplify the PC board layout operation.

## Multiple VCCO pins

To minimize the noise generated in simultaneous switching situations, a minimum of three single-ended outputs per $\mathrm{V}_{\mathrm{CCO}}$ has been employed in the family. Optimum placement of these $\mathrm{V}_{\mathrm{CCO}}$ also results in superior output-to-output skew.

## Advanced Bipolar Processing

The ECLinPS logic family is fabricated using Motorola's MOSAIC III process, a process which is two generations ahead of the process used in the development of the 10 H family. The small geometries and feature sizes of the MOSAIC III process enable the ECLinPS logic family to boast of a nearly three-fold improvement in speed at less than half the power of existing ECL logic families.
The MOSAIC III process is a double polysilicon process which uses a unique self-alignment scheme for device electrode and isolation definition. The process features self aligned submicron emitters as well as polysilicon base, collector and emitter electrodes. In addition, polysilicon resistors, diodes and capacitors are available to minimize the parasitic capacitance of an ECL gate. Figure 1.1 shows a cross section for an NPN device using the MOSAIC III process.

Figure 1.1. MOSAIC III Cross Section

By incorporating the use of polysilicon contacts and resistors through the MOSAIC III process, the parasitic capacitances of an ECLinPS gate are minimized, thus minimizing the time constants which comprise the switching delays of the gate. The resultant gates show delays of 100ps for internal gates and 200ps for output gates capable of driving $50 \Omega$ loads. The small geometries of the process, nearly $350 \%$ reduction in device area compared to a 10 H device, allow these internal gate delays to be achieved at only $800 \mu \mathrm{~A}$ of current.

## Universal Compatibility

Each member of the ECLinPS family is available in both of the existing ECL standards: 10E series devices are compatible with the MECL 10H family; 100E series devices are compatible with ECL 100 K . In addition, to maintain compatibility with temperature-compensated, three-level series-gated gate arrays, the 100E devices are guaranteed to operate without degradation to a $\mathrm{V}_{\mathrm{EE}}$ of -5.46 V .

The section below presents a comparison between the two standards in the new context of the ECLinPS family. The user is also referred to the Electrical Characteristics section of this book as well as appropriate family data books and other literature for descriptive information on the earlier ECL families.

Because no supplier previous to Motorola has offered both ECL standards on an identical process, comparison of existing 10 H and 100 K style devices has some limitations. Comparison of the two standards fabricated with two different processes has sometimes led to the erroneous conclusion that there are inherent AC performance differences between them. In reality this is not the case. The only inherent difference between the two standards is the difference in the behavior of the DC characteristics with temperature.

## AC Performance

From an IC design standpoint the only differences between a 10E device and a 100E device in the ECLinPS family is a small temperature compensation network in the 100E output gate, and very minimal differences in the two bias generator networks. Therefore one would expect that from an AC stand-point the performance of the two standards in the ECLinPS family should be nearly identical; measurements prove this to be the case. There is no significant measurable difference in the rise/fall times, propagation delays or toggle frequencies when comparing a 10E and 100E device. The minor difference between previous 10 H and 100 K designs is due to the fact that the two are fabricated on different processes, and in some cases are designed for operation at different power levels.

## Summary

Summarizing the above information, in general, the two ECL design standards, although differing somewhat in DC parameters, are nearly identical when one compares the AC performance for a given device. There may be very small differences in the AC measurements due to the slightly smaller output swing of the 100E device. However, these differences are negligible when compared to the absolute value of the measurements. Therefore, from an AC stand-point, there is no real advantage in using one standard over the other, thus removing AC performance as a decision variable in high-speed system design.

## Packaging

During the definition phase of the ECLinPS family, much attention was placed on the identification of a suitable package for the family. The package had to meet the criteria of minimum parasitics and propagation delays along with an attractive I/O vs board space relationship. Although the DIP package offered a level of familiarity and convenience, the performance of the package with a very high speed logic family was inadequate. In addition to the obvious parasitics and board space problems, the propagation delays through the DIP package were nearly twice as long as the delay through the silicon.

The 28-pin PLCC package emerged as the clear favorite both internally and with the high speed market in general. The package offers a quad layout to minimize both lead lengths and lead length differences. As a result, the parasitics and delays of the package are very well suited for a high speed logic family. In addition, the nearly matched lead lengths allow for tighter skew among similar paths through the chip.
The board density potential of the PLCC is also attractive in that it allows for a nearly $100 \%$ reduction in board space when compared to the DIP alternative. The package is approximately a half inch square with 50 mil spaced J-bend leads. More detailed measurements can be found in the package section of this data book. The J-bend leads provide a smaller footprint than a gull wing package and propose fewer temperature expansion coefficient mismatch problems than the leadless alternative.
Thermally, the standard PLCC exhibits a $\Theta J A$ of $43.5^{\circ} \mathrm{C}$ per watt at 500 lfpm air flow. With this thermal resistance most 28-pin functions can be implemented with the MOSAIC III process without encountering any severe thermal problems. For more details on thermal issues of the ECLinPS family refer to the thermal section of this data book.

## Abbreviation Definitions

The following is a list of abbreviations found in this data book and a brief definition of each.

## Current

| ICC | Total power supply current drawn from the positive <br> supply by an ECLinPS unit under test. |
| :--- | :--- |
| IEE | Total power supply current drawn from an ECLinPS <br> device under test by the negative supply. |
| IIL | Current drawn by the input of an ECLinPS device with a <br> specified low level (VIL min) forced on the input. |
| IINH | Current drawn by the input of an ECLinPS device with a <br> specified high level (VIH max) forced on the input. |
| IOUT | The current sourced by an output under specified load <br> conditions. |
| Voltage | The switching reference voltage. |
| VBB | Base-to-emitter voltage drop of a transistor at specified <br> collector and base currents. |
| VBE | Collector-to-base voltage drop of a transistor at <br> specified collector and base currents. |
| V |  |

| $\mathrm{V}_{\mathrm{CC}}$ | The most positive supply voltage to an ECLinPS device. |
| :---: | :---: |
| $\mathrm{V}_{\mathrm{CCO}}$ | Power supply connection to the output emitter follower of an ECLinPS gate. For the ECLinPS logic family $\mathrm{V}_{\mathrm{CC}}$ and $\mathrm{V}_{\mathrm{CCO}}$ are common nodes. |
| $V_{\text {EE }}$ | The most negative supply voltage to an ECLinPS device. |
| $\mathrm{V}_{\mathrm{IH}}$ | Nominal input logic HIGH voltage level. |
| $\mathrm{V}_{\mathrm{IH}}$ max | Maximum (most positive) logic HIGH voltage level for which all parametric specifications hold. |
| $\mathrm{V}_{\mathrm{IH}}$ min | Minimum (least positive) logic HIGH voltage level for which all parametric specifications hold. |
| $\mathrm{V}_{\mathrm{IL}}$ | Nominal input logic LOW voltage. |
| $\mathrm{V}_{\text {IL }}$ max | Maximum (most positive) logic LOW voltage level for which all parametric specifications hold. |
| $\mathrm{V}_{\text {IL }}$ min | Minimum (least positive) logic HIGH voltage level for which all parametric specifications hold. |
| $\mathrm{V}_{\mathrm{OH}}$ | Output logic HIGH voltage level for the specified load condition. |
| $\mathrm{V}_{\text {OHA }}$ | Output logic HIGH voltage level with the inputs biased at $\mathrm{V}_{\mathrm{IH}}$ min or $\mathrm{V}_{\mathrm{OL}}$ max. |
| $\mathrm{V}_{\mathrm{OH}}$ max | Maximum (most positive) logic HIGH output voltage level. |
| $\mathrm{V}_{\mathrm{OH}}$ min | Minimum (least positive) logic HIGH output voltage level. |
| $\mathrm{V}_{\mathrm{OL}}$ | Output logic LOW voltage level for the specified load condition. |
| VOLA | Output logic LOW voltage level with the inputs biased at $\mathrm{V}_{\mathrm{IH}}$ min or $\mathrm{V}_{\mathrm{OL}}$ max. |
| $\mathrm{V}_{\text {OL }}$ max | Maximum (most positive) logic LOW output voltage level. |
| $\mathrm{V}_{\mathrm{OL}}$ min | Minimum (least positive) logic LOW output voltage level. |
| $\mathrm{V}_{\mathrm{TT}}$ | Output termination voltage for ECLinPS open emitter follower outputs. |
| $V_{\text {PP }}$ | Minimum peak-to-peak input voltage for differential input devices. |
| $\mathrm{V}_{\text {CMR }}$ | The voltage range in which the logic HIGH voltage level of a differential input signal must fall for a differential input device. |

VCUT The logic LOW voltage level for ECL BUS outputs which attain cutoff of the output emitter follower.
$V_{\text {SUP }} \quad$ The maximum voltage difference between $\mathrm{V}_{\mathrm{EE}}$ and $\mathrm{V}_{\mathrm{CC}}$ for the E1651 comparator.

## Timing Parameters

tR Waveform rise time of an output signal measured from the $20 \%$ to $80 \%$ levels of the signal.
tF Waveform fall time of an output signal measured from the $20 \%$ to $80 \%$ levels of the signal.

TPD $\pm \pm$ Propagation delay of a signal measured for a rising/falling input to a rising/falling output.
xpt The crossing point of a differential input or output signal. The reference point for which differential delays are measured.

TPLH The propagation delay for an output transitioning from a logic LOW level to a logic HIGH level.

TPHL The propagation delay for an output transitioning from a logic HIGH level to a logic LOW level.
fMAX Maximum input frequency for which an ECLinPS flip flop will function correctly.
fCOUNT Maximum input frequency for which an ECLinPS counter will function properly.
fSHIFT Maximum input frequency for which an ECLinPS shift register will function properly.
tSKEW The maximum delay difference between similar paths on a single ECLinPS device.
$t_{s} \quad$ Setup time: the minimum amount of time an input must transition before a clock transition to ensure proper function of the device.
$\mathrm{t} \mathrm{H} \quad$ Hold time: the minimum amount of time an input must remain asserted after a clock transition to ensure proper operation of the device.
tRR Release time or Reset Recovery Time: the minimum amount of time after a signal is de-asserted that a different input must wait before assertion to ensure proper functionality of the device.
$t_{w}$ min Minimum pulse width of a signal necessary to ensure proper functionality of a device.

## Temperature

\(\left.$$
\begin{array}{ll}\text { TSTG } & \begin{array}{l}\text { The maximum temperature at which a device may be } \\

## Miscellaneous

DUT Device under test.
CIN Input capacitance of a device.
$Z_{I N} \quad$ Input impedance of a device.
COUT Output capacitance of a device.
ZOUT Output impedance of a device.

PD The total dc power applied to a device, not including any power delivered from the device to the load.
$R_{L} \quad$ Load resistance.
$\mathrm{R}_{\boldsymbol{T}} \quad$ Transmission line termination resistor.
Rp An input pull-down resistor.
PUT Pin under test.
SMA Industry standard PCB connector.

# SECTION 5 Electrical Characteristics 

## DC Characteristics

## ECLinPS* Transfer Curves

As mentioned in the previous section, except for the E1651, E1652 and E197 all ECLinPS devices are offered in either 10E or 100E versions to be compatible with 10 H or 100 K ECL logic respectively. The following information will overview the DC characteristics of the two versions of ECLinPS devices, for more detailed discussions the reader is referred to the MECL and F100K data books.
Both 10 E and 100 E devices produce $\approx 800 \mathrm{mV}$ output swings into a specified $50 \Omega$ to -2.0 V load. However, because of the low output impedance (Figure 2.1) of both standards, neither is limited to $50 \Omega$ loads. Larger load resistances can be used to reduce the system power without sacrificing the speed of the device. Of course the overall system speed will be reduced due to the increased delays of the interconnect traces. In addition, to better drive high capacitive lines, smaller resistances, down to $25 \Omega$, can be used without violating the 50 mA max output current specification. It is however recommended that for lines of less than $35 \Omega$, specialized $25 \Omega$ driver circuits or "ganged" output schemes should be used to ensure optimum long term reliability of the device.

Figure 2.1. Output Characteristics vs Load

The 10E devices are voltage compensated but not temperature compensated, therefore, although the output voltage levels are insensitive to variations in $\mathrm{V}_{\mathrm{EE}}$, they do vary with temperature. The transfer curves in Figure 2.2 pictorially illustrate the behavior of the 10E outputs. In order to maintain noise margins over temperature, it is important that the $V_{B B}$ switching reference tracks with temperature in such a way as to remain centered between the VOH and $\mathrm{V}_{\mathrm{OL}}$ levels. As shown in Table 2.1, the temperature tracking rates of the VOH and $\mathrm{V}_{\mathrm{OL}}$ for a 10E device are not equal. Therefore, it is necessary to design the $V_{B B}$ reference such that it tracks at a rate equal to the average rate of the difference between the

Figure 2.2. ECLinPS 10E Transfer Curves

[^1]high and low output level tracking rates. Table 2.1 also outlines the temperature tracking behavior of a $10 \mathrm{E} \mathrm{V}_{\mathrm{BB}}$ switching reference.

| 10 E | min | typ | max |
| :---: | :---: | :---: | :---: |
| $\Delta \mathrm{V}_{\mathrm{OH}} / \Delta \mathrm{T}\left(\mathrm{mV} /{ }^{\circ} \mathrm{C}\right)$ | 1.1 | 1.2 | 1.4 |
| $\Delta \mathrm{~V}_{\mathrm{OL}} / \Delta \mathrm{T}\left(\mathrm{mV} /{ }^{\circ} \mathrm{C}\right)$ | 0 | 0.4 | 0.6 |
| $\Delta \mathrm{~V}_{\mathrm{BB}} / \Delta \mathrm{T}\left(\mathrm{mV} /{ }^{\circ} \mathrm{C}\right)$ | 0.6 | 0.8 | 1.0 |
| $\Delta \mathrm{~V}_{\mathrm{OH}} / \Delta \mathrm{V}_{\mathrm{EE}}(\mathrm{mV} / \mathrm{V})$ | 0 | 5 | 20 |
| $\Delta \mathrm{~V}_{\mathrm{OL}} / \Delta \mathrm{V}_{\mathrm{EE}}(\mathrm{mV} / \mathrm{V})$ | 0 | 10 | 30 |
| $\Delta \mathrm{~V}_{\mathrm{BB} / \Delta \mathrm{V}_{\mathrm{EE}}(\mathrm{mV} / \mathrm{V})}$ | 0 | 5 | 20 |
| $\mathbf{1 0 0 E}$ | min | typ | max |
| $\Delta \mathrm{V}_{\mathrm{OH} /} / \Delta \mathrm{T}\left(\mathrm{mV} /{ }^{\circ} \mathrm{C}\right)$ | -0.15 | 0 | 0.15 |
| $\Delta \mathrm{~V}_{\mathrm{OL}} / \Delta \mathrm{T}\left(\mathrm{mV} /{ }^{\circ} \mathrm{C}\right)$ | -0.30 | 0 | 0.30 |
| $\Delta \mathrm{~V}_{\mathrm{BB}} / \Delta \mathrm{T}\left(\mathrm{mV} /{ }^{\circ} \mathrm{C}\right)$ | -0.20 | 0 | 0.20 |
| $\Delta \mathrm{~V}_{\mathrm{OH}} / \Delta \mathrm{V}_{\mathrm{EE}}(\mathrm{mV} / \mathrm{V})$ | 0 | 5 | 20 |
| $\Delta \mathrm{~V}_{\mathrm{OL}} / \Delta \mathrm{V}_{\mathrm{EE}}(\mathrm{mV} / \mathrm{V})$ | 0 | 10 | 30 |
| $\Delta \mathrm{~V}_{\mathrm{BB} / \Delta \mathrm{V}_{\mathrm{EE}}(\mathrm{mV} / \mathrm{V})}$ | 0 | 5 | 20 |

Table 2.1. ECLinPS Voltage Level Tracking Rates
The 100E devices, on the other hand, are temperature and voltage compensated, therefore, the output levels remain fairly constant over variations in both $\mathrm{V}_{\mathrm{EE}}$ and temperature. Figure 2.3 shows the transfer characteristics for a 100E device. The associated tracking rates are illustrated in Table 2.1. Notice that in this case the $\mathrm{V}_{\mathrm{BB}}$ switching reference is designed to remain constant over temperature to maintain an optimum position within the output swing of the device. This flat temperature tracking of the internal reference levels leads to a phenomena particular to the 100E devices.

Figure 2.3. ECLinPS 100E Transfer Characteristics

Since the $V_{B E S}$ of the current source transistor reduce with temperature, if the current source reference remains constant, as is the case for 100E devices, the IEE of the device will vary with temperature. Careful scrutiny of the data sheets will reveal that the worst case IEE for a function is higher for the 100E version than the 10E version of that device. As a result, from a power standpoint a 100E device operating at $85^{\circ} \mathrm{C}$ with a -4.5 V VEE will be nearly identical to a 10 E device operating with $\mathrm{a}-5.2 \mathrm{~V}$ VEE under identical temperature conditions.
Although differing somewhat in many DC parameters, 10E and 100E devices do share a couple of the same DC characteristics. Both designs show superior IEE vs VEE tracking rates due to the design of the voltage regulator. With a tracking rate of $<3 \% / \mathrm{V}$, this variation can effectively be ignored during system design. The output level and reference level variation with $\mathrm{V}_{\mathrm{EE}}$ are also outstanding as can be seen in Table 2.1.

## Noise Margin

The noise margin of a device is a measure of a device's resistance to undesirable switching. For ECLinPS, as well as all ECL devices, noise margin is a DC specification. The noise margin is defined as the difference between the voltage level of an output of the sending device and the required voltage level of the input of the receiving device. Therefore a worst case noise margin can be calculated from the ECLinPS data sheets by simply subtracting the $\mathrm{V}_{\mathrm{IL}}$ max or $\mathrm{V}_{I H}$ min from the $\mathrm{V}_{\mathrm{OL}}$ min or $\mathrm{VOH}_{\mathrm{OH}}$ max respectively. Table 2.2 below illustrates the worst case and typical noise margins for both 10E and 100E ECLinPS devices. Notice that the typical noise margins are approximately 100 mV larger than the worst case.

|  | 10E |  | 100E |  |
| :--- | :---: | :---: | :---: | :---: |
|  | min | typ | min | typ |
| NM $_{\text {HIGH }}(\mathrm{mV})$ | 150 | 240 | 140 | 210 |
| NM $_{\text {LOW }}(\mathrm{mV})$ | 150 | 280 | 145 | 230 |

## Table 2.2. DC Noise Margins

As mentioned above, the noise margins of a device are a DC measurement and thus can lead to some false impressions of the noise immunity of a system. For instance, from the chart the worst case noise margin is 140 mV for a high level of a 100E device. This would suggest that an undershoot on this line of greater than 140 mV could cause an error in the system. This however is not necessarily the case as the determination as to whether or not an AC noise signal is propagated is dependent on line impedances, output impedances and propagation delays as well as noise margins.

## AC Characteristics

## Parameter Definitions

The device data sheets in Section 3 contain specifications for the propagation delays and rise/fall times for each of the devices in the ECLinPS family. In addition, where applicable, skew, setup/hold, maximum toggle frequencies (fMAX), reset recovery and minimum pulse width specifications are included. The waveforms and terminologies used in describing the propagation delays and rise/fall times of the ECLinPS family are depicted in Figure 2.4 below.

SINGLE-ENDED PROPAGATION DELAY

Figure 2.4. ECLinPS TPD Measurement Waveforms

Propagation delays and rise/fall times are generally well understood parameters, however, there is sometimes confusion surrounding the definitions of more specialized AC parameters such as skew, setup/hold times, release times, and maximum frequency. The following few paragraphs will outline the ways in which Motorola defines these parameters.

## Skew Times

In the design of high speed systems skew plays nearly as important a role as propagation delay. The majority of the devices in the ECLinPS family have the skew between outputs specified. This skew specification represents the typical difference between the delays of similar paths on a single chip. No maximum value for skew is specified due to the difficulty in the production testing of this parameter. The user is encouraged to contact an ECLinPS application engineer to obtain actual evaluation data if this parameter is critical in their designs.

## Set-Up and Hold Times

Motorola defines the setup time of a device as the minimum time, prior to the transition of the clock, that an input must be stable to ensure that the device operates properly. The hold time, on the other hand, is defined as the minimum time that an input must remain stable after the transition of the clock to ensure that the device operates properly. Figure 2.5 illustrates the way in which Motorola defines setup and hold times.

Figure 2.5. Set-Up and Hold Waveforms

## Release Times

Release times are defined as the minimum amount of time an input must wait to be clocked after an enable, master reset or set signal is deactivated to ensure proper operation. Because more times than not this specification is in reference to a master reset operation, this parameter is often called reset recovery time. Figure 2.6 illustrates the definition of release time in the Motorola data sheets.

Figure 2.6. ECLinPS Release Time Waveforms

## fMAX Measurement

In general f MAX is measured in the manner shown in Figure 2.7 with the fail criterion being either a swing of 600 mV or less, or a miscount. However, in some cases, the feedback method of testing can lead to a pessimistic value of $f$ MAX because the feedback path delay is such that the setup times of the device are violated. If this is the case, it is necessary to have two free running signal generators to ensure that the setup times are observed. This parameter, along with fSHIFT and fCOUNT, represents the maximum frequency at which a particular flip flop, shift register or counter can be clocked with the divide, shift or count operation guaranteed. This number is generated from worst case operating conditions, thus, under nominal operating conditions, the maximum toggle frequency is higher.

## AC Testing ECLinPS Devices

The introduction of the ECLinPS family raised the performance of silicon to a new domain. As the propagation delays of logic devices become ever faster the task of

Figure 2.7. fMAX Measurement
correlating between test setups becomes increasingly challenging. To obtain test results which correlate with Motorola, various testing techniques must be adhered to. A typical schematic for an ECLinPS test setup is illustrated in Figure 2.8.

A solid ground plane is a must in the test setup, as the two power supplies are bypassed to this ground plane. A $20 \mu \mathrm{~F}$ capacitor from the two power supplies to ground is used to dampen any supply variations. An RF quality $0.01 \mu \mathrm{~F}$ capacitor from each power pin to ground is used to decouple the fixture. These $0.01 \mu \mathrm{~F}$ capacitors should be located as close to the power pins of the package as possible. In addition, in order to minimize the inductance of the power pins, all of the power leads should be kept as short as possible. The power supplies are shifted by +2.0 V so that the load comprises only the precision $50 \Omega$ input impedance of the oscilloscope. Use of this technique will assure that the customer and Motorola are terminating devices into equivalent loads and will improve test correlation.

Figure 2.8. Typical ECLinPS Test Setup

## Electrical Characteristics

To further standardize testing, any unused outputs should be loaded with $50 \Omega$ to ground.
Because the power supplies are shifted, the input levels must also be shifted by an equal amount. Table 2.3 gives the typical input levels for the ECLinPS family and their corresponding +2.0 V shifted levels.

| 10Exxx | Typical | Shifted |
| :---: | :---: | :---: |
| $\mathrm{V}_{\mathrm{IL}}$ | -1.75 V | +0.25 V |
| $\mathrm{~V}_{\mathrm{IH}}$ | -0.90 V | +1.10 V |
| $\mathbf{1 0 0 E x x x}$ | Typical | Shifted |
| $\mathrm{V}_{\mathrm{IL}}$ | -1.70 V | +0.30 V |
| $\mathrm{~V}_{\mathrm{IH}}$ | -0.95 V | +1.05 V |

Table 2.3. ECL Levels after Translating by +2.0V

The test fixture should be in a controlled impedance $50 \Omega$ environment, with any non-50 $\Omega$ interconnects, or stubs, kept as short as possible ( $<1 / 4^{\prime \prime}$ ). This controlled impedance environment will help to minimize overshoot and ringing, two phenomena which can lead to inaccuracies in AC measurements. To minimize degradation of the input and output edge rates, a $50 \Omega$ coaxial cable with a teflon dielectric is recommended, however any other cable with a bandwidth of $>5.0 \mathrm{GHz}$ is adequate. In addition, the cables from the device under test (DUT) to the inputs of the scope
should be matched in length to prevent any errors due to different path lengths from the DUT to the scope. The interconnect fittings should be $50 \Omega$ SMA straight or SMA launchers to minimize impedance mismatches at the interface of the coax and test PC board. Although a teflon laminate board is preferable, an FR4 laminate board is acceptable as long as the signal traces are kept to five inches or less. Longer traces will result in significant edge rate degradation of the input and output signals.
To make the board useful for incoming inspection or other volume testing, the board needs to be fitted with a socket. Although not suitable for AC testing due to different pin lengths and large parasitics, there are through hole sockets which are adequate for DC testing of ECLinPS devices. For AC testing purposes a 28-pin PLCC surface mount socket is recommended.
To ease the correlation issue, Motorola has developed a universal AC test board which is now available to customers. The board is fitted with a PLCC socket and comes with instructions on how it can be configured for the different device types in the family. For ordering information see the description on the following page.
Finally, to ensure correlation between Motorola and the customer, high-performance, state-of-the-art measuring equipment should be used. The pulse generator must be capable of producing the required input levels with rise and fall times of 500 ps . In addition, if f MAX is going to be tested, a frequency of up to 1.5 GHz may be needed. The oscilloscope should also be of the utmost in performance with a minimum bandwidth of 5.0 GHz .

# SECTION 6 <br> Engineering Evaluation Board for 28-Pin ECL Devices in the PLCC Package Part \# ECLPSBD28 

## DESCRIPTION

This board is designed to provide a low cost characterization tool for evaluating ECL devices in the ECLinPS Product Family. The board provides a high bandwidth $50 \Omega$ controlled impedance environment. The board is universal and can be configured by the user for any of the 28-pin PLCC devices in the family depending on the input, output, and power pinout layout of the device. The table below indicates common input/output/power devices.

| Group | Base Device | Pin Compatible Devices |

| CONF15 | E193 |  |

Table 1. Cross Reference of Board Configurations

The board is designed to test devices using the fly-by (Kelvin contact) test method, therefore one input force trace and one input sense trace exist for each input pin. This allows termination of the input and output signals into the highly accurate 50 ohm impedance of an oscilloscope. The layout is engineered to have equal length traces from the device under test (DUT) socket to the sense outputs which simplifies the calibration requirements for accurate AC measurements.

The kit provides a printed circuit board with an attached surface mount socket as well as assembly instructions. For superior impedance control from the cable to the board, Motorola recommends the use of SMA coaxial connectors.

## ASSEMBLING THE ECLinPS EVALUATION BOARD

The evaluation board is designed for characterizing devices in a laboratory environment using high bandwidth sampling oscilloscopes such as the Hewlett Packard 54120T, the Tektronix 11800 Series, or the Tektronix 7854. The board is designed using Kelvin contact (fly-by) techniques to present the input signals to the DUT. Each pin on the board has two traces, one force and one sense. Input pins use one force and one sense line, while outputs need only a sense line. This means that input signals are terminated through the sense line into the 50 ohm input of a sampling oscilloscope instead of at the input to the DUT. Please refer to the AC Testing section of the ECLinPS Data Book for further information and a simplified figure of the test setup.

The first step in building a board is determining which input/output/power configuration is necessary for the device of interest. Table 1 on the first page of the Applications Information shows all the board configurations. For example, if the devices of interest were the E104 and the E151, then CONF2 would be selected. Table 2 is a pin cross reference for each configuration.

## I. Installing the SMA Connectors

Table 2 indicates the number of SMA connectors needed to populate an evaluation board for a given configuration. Depending on the device and the parameters of interest, it may not be necessary to install the full complement of SMA connectors. For example, some devices have two clock inputs or common clocks and individual clocks. Figure 1 is the frontview of the ECLinPS evaluation board. Item A points to the inner ring which connects to the sense traces of the DUT. The outer ring connects to the force traces. An input requires one SMA connector for the force and one SMA connector for the sense, while an output only requires a connection to the sense trace. Insert all the SMA connectors into the board and solder to the board. A simple assembly technique is to place a stiff piece of cardboard ( $8^{\prime \prime} \times 7^{\prime \prime}$ or larger) on top of all the connectors and hold the board and cardboard together. Invert the board, place on a level surface, and all the connectors will be seated properly and can be soldered in place.

## II. Connecting Power Planes to DUT Socket

There are four voltage planes on the ECLPSBD28. One is dedicated to ground and the other three, B1, B2, B3, are uncommitted. These planes are accessible through a power connection and sets of four vias that are adjacent to each sense trace. This is identified as Item B in Figure 1. For standard parts, B 1 can be assigned $\mathrm{V}_{\mathrm{CC}}$, B 2 can be assigned to $\mathrm{V}_{\mathrm{EE}}$, and B 3 can be assigned to ground. Table 2 indicates which pins need to be connected to the various supply voltages. On the front side of the board, solder a jumper wire from the closest $\mathrm{V}_{E E}$ or $\mathrm{V}_{\mathrm{C}}$ via to the sense trace for each $\mathrm{V}_{\mathrm{CC}}, \mathrm{V}_{\mathrm{CCO}}$, and $\mathrm{V}_{\mathrm{EE}}$ pin. Near the DUT there are sets of ground/bias plane vias that accommodate power supply decoupling capacitors. These are identified as Item C. On the front side of the board install $10 \mu \mathrm{~F}$ capacitors and on the back side install a $0.01 \mu \mathrm{~F}$ high frequency capacitor in parallel to decouple the $\mathrm{V}_{\mathrm{EE}}$ and $\mathrm{V}_{\mathrm{CC}}$ planes.

## III. Cutting Force Traces for Outputs

Because of the design of the board, all force traces for output pins will appear as transmission line stubs connected to the output pin. On the back side of the board, cut the force traces associated with the outputs using a razor blade knife. It is important to cut the trace very close to the DUT area to minimize the stub length. Also cut the force traces that are connected to $\mathrm{V}_{\mathrm{CC}}, \mathrm{V}_{\mathrm{CCO}}$, and $V_{E E}$ pins.

## IV. Installing the Chip Capacitors for the VCc/Vcco Pins

In the kit are $0.01 \mu \mathrm{~F}$ chip capacitors for use in decoupling the $\mathrm{V}_{\mathrm{CC}}$ and $\mathrm{V}_{\mathrm{CCO}}$ pins to the ground plane. This is critical because the power pins are not directly connected to the $\mathrm{V}_{\mathrm{CC}}$ plane as in an actual board layout. On the back side of the board beneath the DUT socket are pads for each pin which allow connection of chip capacitors to the center island (GND) for each VCC and VCCO pin. Stand the chip capacitors on edge when soldering them in place so that adjacent pins are not shorted together.

## V. Final Assembly

The board power plane interface is designed to accommodate a 15-pin right angle D connector. This can be used directly, or wires can be inserted into the vias to connect to the power planes that were connected to the DUT in part II. Attach standoffs into the four 0.25 inch holes at the corners of the board. This completes the assembly of the evaluation board and it should be ready to test.

## VI. SMA Connector Suppliers

Below are two suppliers who manufacture PC Mount SMA connectors which interface to the evaluation board. Motorola has used these two connectors before, but there are other vendors who manufacture similar products.

1. 10E series circuits are designed to meet the dc specifications shown in the table, after thermal equilibrium has been established. The circuit is in a test socket or mounted on a printed circuit board and transverse air flow greater than 500 lfpm is maintained. Outputs are terminated through a $50 \Omega$ resistor to -2.0 volts, except bus outputs which, where specified, are terminated into $25 \Omega$.

## 100E Series DC Characteristics

$\mathrm{V}_{\mathrm{EE}}=-4.2 \mathrm{~V}$ to $-5.46 \mathrm{~V} ; \mathrm{V}_{\mathrm{CC}}=\mathrm{V}_{\mathrm{CCO}}=\mathrm{GND} ; \mathrm{T}_{\mathrm{A}}=0^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$

| Symbol | Characteristic | Min | Typ | Max | Unit | Conditions |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $\mathrm{V}_{\mathrm{OH}}$ | Output HIGH Voltage | -1025 | -955 | -880 | mV | $\mathrm{V}_{\mathrm{IN}}=\mathrm{V}_{\mathrm{IH}}(\max )$ | Loading with $50 \Omega$ to -2.0 V |
| $\mathrm{V}_{\mathrm{OL}}$ | Output LOW Voltage | -1810 | -1705 | -1620 | mV | or $\mathrm{V}_{\mathrm{IL}}$ (min) |  |
| V OHA | Output HIGH Voltage | -1035 |  |  | mV | $\mathrm{V}_{\mathrm{IN}}=\mathrm{V}_{\mathrm{IH}}(\mathrm{min})$ |  |
| $\mathrm{V}_{\text {OLA }}$ | Output LOW Voltage |  |  | -1610 | mV | or $\mathrm{V}_{\text {IL }}$ (max) |  |
| $\mathrm{V}_{\mathrm{IH}}$ | Input HIGH Voltage | -1165 |  | -880 | mV | Guaranteed HIGH Signal for All Inputs |  |
| $\mathrm{V}_{\text {IL }}$ | Input LOW Voltage | -1810 |  | -1475 | mV | Guaranteed LOW Signal for All Inputs |  |
| $\mathrm{I}_{\text {IL }}$ | Input LOW Current | 0.5 |  |  | $\mu \mathrm{A}$ | $\mathrm{V}_{\text {IN }}=\mathrm{V}_{\text {IL }}(\mathrm{min})$ |  |

This table replaces the three tables at different supply voltages in the previous edition and in ECL 100K literature. The same DC parametric values at $\mathrm{V}_{\mathrm{EE}}=-4.5 \mathrm{~V}$ now apply across the full $\mathrm{V}_{\mathrm{EE}}$ range of -4.2 to -5.46 V .

## 8-Bit Synchronous Binary Up Counter

The MC10E/100E016 is a high-speed synchronous, presettable, cascadable 8-bit binary counter. Architecture and operation are the same as the MC10H016 in the MECL 10H family, extended to 8-bits, as shown in the logic symbol.

The counter features internal feedback of $\overline{\mathrm{TC}}$, gated by the TCLD (terminal count load) pin. When TCLD is LOW (or left open, in which case it is pulled LOW by the internal pull-downs), the TC feedback is disabled, and counting proceeds continuously, with TC going LOW to indicate an all-one state. When TCLD is HIGH, the TC feedback causes the counter to automatically reload upon TC $=$ LOW, thus functioning as a programmable counter. The $Q_{n}$ outputs do not need to be terminated for the count function to operate properly. To minimize noise and power, unused $Q$ outputs should be left unterminated.

- 700MHz Min. Count Frequency
- 1000ps CLK to Q, TC
- Internal TC Feedback (Gated)
- 8-Bit
- Fully Synchronous Counting and TC Generation
- Asynchronous Master Reset
- Extended 100E VEE Range of -4.2 V to -5.46 V
- $75 \mathrm{k} \Omega$ Input Pulldown Resistors

Pinout: 28-Lead PLCC (Top View)

* All $\mathrm{V}_{\mathrm{CC}}$ and $\mathrm{V}_{\mathrm{CCO}}$ pins are tied together on the die.

## 8-BIT BINARY COUNTER LOGIC DIAGRAM

Note that this diagram is provided for understanding of logic operation only.
It should not be used for propagation delays as many gate functions are achieved internally without incurring a full gate delay.

## Applications Information

## Cascading Multiple E016 Devices

For applications which call for larger than 8-bit counters multiple E016s can be tied together to achieve very wide bit width counters. The active low terminal count (TC) output and count enable input (CE) greatly facilitate the cascading of E016 devices. Two E016s can be cascaded without the need for external gating, however for counters wider than 16 bits external OR gates are necessary for cascade implementations.
Figure 1 below pictorially illustrates the cascading of 4 E016s to build a 32-bit high frequency counter. Note the E101 gates used to OR the terminal count outputs of the lower order E016s to control the counting operation of the higher order bits. When the terminal count of the preceding device (or devices) goes low (the counter reaches an all 1s state) the more significant E016 is set in its count mode and will count one binary digit upon the next positive clock transition. In addition, the preceding devices will also count one bit thus sending their terminal count outputs back to a high state
disabling the count operation of the more significant counters and placing them back into hold modes. Therefore, for an E016 in the chain to count, all of the lower order terminal count outputs must be in the low state. The bit width of the counter can be increased or decreased by simply adding or subtracting E016 devices from Figure 1 and maintaining the logic pattern illustrated in the same figure.

The maximum frequency of operation for the cascaded counter chain is set by the propagation delay of the TC output and the necessary setup time of the CE input and the propagation delay through the OR gate controlling it (for 16-bit counters the limitation is only the TC propagation delay and the CE setup time). Figure 1 shows EL01 gates used to control the count enable inputs, however, if the frequency of operation is lower a slower, ECL OR gate can be used. Using the worst case guarantees for these parameters from the ECLinPS data book, the maximum count frequency for a greater than 16-bit counter is 500 MHz and that for a 16 -bit counter is 625 MHz .

Figure 1. 32-Bit Cascaded E016 Counter

## Applications Information (continued)

Note that this assumes the trace delay between the TC outputs and the CE inputs are negligible. If this is not the case estimates of these delays need to be added to the calculations.

## Programmable Divider

The E016 has been designed with a control pin which makes it ideal for use as an 8 -bit programmable divider. The TCLD pin (load on terminal count) when asserted reloads the data present at the parallel input pin (Pn's) upon reaching terminal count (an all 1s state on the outputs). Because this feedback is built internal to the chip, the programmable division operation will run at very nearly the same frequency as the maximum counting frequency of the device. Figure 2 below illustrates the input conditions necessary for utilizing the E016 as a programmable divider set up to divide by 113.

Figure 2. Mod 2 to 256 Programmable Divider
To determine what value to load into the device to accomplish the desired division, the designer simply subtracts the binary equivalent of the desired divide ratio from the binary value for 256. As an example for a divide ratio of 113:

Pn's $=256-113=8 F_{16}=10001111$
where:
P0 = LSB and P7 = MSB

Forcing this input condition as per the setup in Figure 2 will result in the waveforms of Figure 3. Note that the TC output is used as the divide output and the pulse duration is equal to a

full clock period. For even divide ratios, twice the desired divide ratio can be loaded into the E016 and the TC output can feed the clock input of a toggle flip flop to create a signal divided as desired with a 50\% duty cycle.

A single E016 can be used to divide by any ratio from 2 to 256 inclusive. If divide ratios of greater than 256 are needed multiple E016s can be cascaded in a manner similar to that already discussed. When E016s are cascaded to build larger dividers the TCLD pin will no longer provide a means for loading on terminal count. Because one does not want to reload the counters until all of the devices in the chain have reached terminal count, external gating of the TC pins must be used for multiple E016 divider chains.

Figure 3. Divide by 113 E016 Programmable Divider Waveforms

Applications Information (continued)

Figure 4. 32-Bit Cascaded E016 Programmable Divider

Figure 4 on the following page shows a typical block diagram of a 32-bit divider chain. Once again to maximize the frequency of operation EL01 OR gates were used. For lower frequency applications a slower OR gate could replace the EL01. Note that for a 16 -bit divider the OR function feeding the PE (program enable) input CANNOT be replaced by a wire OR tie as the TC output of the least significant E016 must also feed the CE input of the most significant E016. If the two TC outputs were OR tied the cascaded count operation would not operate properly. Because in the cascaded form the PE feedback is external and requires external gating, the maximum frequency of operation will be significantly less than the same operation in a single device.

## Maximizing E016 Count Frequency

The E016 device produces 9 fast transitioning single ended outputs, thus $\mathrm{V}_{\mathrm{CC}}$ noise can become significant in situations where all of the outputs switch simultaneously in the same direction. This $\mathrm{V}_{\mathrm{CC}}$ noise can negatively impact the maximum frequency of operation of the device. Since the device does not need to have the Q outputs terminated to count properly, it is recommended that if the outputs are not going to be used in the rest of the system they should be left unterminated. In addition, if only a subset of the Q outputs are used in the system only those outputs should be terminated. Not terminating the unused outputs will not only cut down the $\mathrm{V}_{\mathrm{CC}}$ noise generated but will also save in total system power dissipation. Following these guidelines will allow designers to either be more aggressive in their designs or provide them with an extra margin to the published data book specifications.

## Quad 4-Input OR/NOR Gate

The MC10E/100E101 is a quad 4-input OR/NOR gate.

1. Within-device skew is defined as identical transitions on similar paths through a device.

## 1:9 Differential Clock Driver

The MC10E/100E111 is a low skew 1-to-9 differential driver, designed with clock distribution in mind. It accepts one signal input, which can be either differential or else single-ended if the $\mathrm{V}_{\mathrm{BB}}$ output is used. The signal is fanned out to 9 identical differential outputs. An enable input is also provided. A HIGH disables the device by forcing all Q outputs LOW and all Q outputs HIGH.

- Low Skew
- Guarateed Skew Spec
- Differential Design
- $V_{B B}$ Output
- Enable
- Extended 100E VEE Range of -4.2 to -5.46 V
- $75 \mathrm{k} \Omega$ Input Pulldown Resistors

The device is specifically designed, modeled and produced with low skew as the key goal. Optimal design and layout serve to minimize gate to gate skew within-device, and empirical modeling is used to determine process control limits that ensure consistent tpd distributions from lot to lot. The net result is a dependable, guaranteed low skew device.

To ensure that the tight skew specification is met it is necessary that both sides of the differential output are terminated into $50 \Omega$, even if only one side is being used. In most applications, all nine differential pairs will be used and therefore terminated. In the case where fewer than nine pairs are used, it is necessary to terminate at least the output pairs on the same package side (i.e. sharing the same $\mathrm{V}_{\mathrm{CCO}}$ ) as the pair(s) being used on that side, in order to maintain minimum skew. Failure to do this will result in small degradations of propagation delay (on the order of $10-20 \mathrm{ps}$ ) of the output(s) being used which, while not being catastrophic to most designs, will mean a loss of skew margin.

1. The differential propagation delay is defined as the delay from the crossing points of the differential input signals to the crossing point of the differential output signals. See Definitions and Testing of ECLinPS AC Parameters in Chapter 1 (page 1-12).
2. The single-ended propagation delay is defined as the delay from the $50 \%$ point of the input signal to the $50 \%$ point of the output signal. See Definitions and Testing of ECLinPS AC Parameters in Chapter 1 (page 1-12).
3. Enable is defined as the propagation delay from the $50 \%$ point of a negative transition on $\overline{E N}$ to the $50 \%$ point of a positive transition on $Q$ (or a negative transition on Q). Disable is defined as the propagation delay from the $50 \%$ point of a positive transition on EN to the $50 \%$ point of a negative transition on $Q$ (or a positive transition on $Q$ ).
4. The within-device skew is defined as the worst case difference between any two similar delay paths within a single device.
5. The setup time is the minimum time that EN must be asserted prior to the next transition of IN/IN to prevent an output response greater than $\pm 75 \mathrm{mV}$ to that IN/IN transition (see Figure 1).
6. The hold time is the minimum time that EN must remain asserted after a negative going IN or a positive going IN to prevent an output response greater than $\pm 75 \mathrm{mV}$ to that $\mathrm{IN} / \mathrm{IN}$ transition (see Figure 2).
7. The release time is the minimum time that EN must be deasserted prior to the next IN/IN transition to ensure an output response that meets the specified IN to Q propagation delay and output transition times (see Figure 3).
8. $\mathrm{V}_{\mathrm{PP}}(\mathrm{min})$ is defined as the minimum input differential voltage which will cause no increase in the propagation delay. The $\mathrm{V}_{\mathrm{PP}}(\mathrm{min})$ is AC limited for the E111 as a differential input as low as 50 mV will still produce full ECL levels at the output.

Figure 3. Release Time

## Quad Driver

The MC10E/100E112 is a quad driver with two pairs of OR/NOR outputs from each gate, and a common, buffered enable input. Using the data inputs the device can serve as an ECL memory address fan-out driver. Using just the enable input, the device serves as a clock driver, although the MC10E/100E111 is designed specifically for this purpose, and offers lower skew than the E112. For memory address driver applications where scan capabilities are required, please refer to the E212 device.

- 600ps Max. Propagation Delay
- Common Enable Input
- Extended 100E VEE Range of -4.2 V to -5.46 V
- $75 \mathrm{k} \Omega$ Input Pulldown Resistors

Pinout: 28-Lead PLCC (Top View)

* All $\mathrm{V}_{\mathrm{CC}}$ and $\mathrm{V}_{\mathrm{CCO}}$ pins are tied together on the die.

1. Within-device skew is defined as identical transitions on similar paths through a device.
2. Skew defined between common OR or common NOR outputs of a single gate.

## Quint Differential Line Receiver

The MC10E/100E116 is a quint differential line receiver with emitter-follower outputs. An internally generated reference supply ( $V_{B B}$ ) is available for single-ended reception.

- 500ps Max. Propagation Delay
- VBB Supply Output
- Dedicated $\mathrm{V}_{\mathrm{CCO}}$ Pin for Each Receiver
- Extended 100E VEE Range of -4.2 V to -5.46 V
- $75 \mathrm{k} \Omega$ Input Pulldown Resistors

Active current sources plus a deep collector feature of the MOSAIC III process provide the receivers with excellent common-mode noise rejection. Each receiver has a dedicated $\mathrm{V}_{\mathrm{CCO}}$ supply lead, providing optimum symmetry and stability.

The receiver design features clamp circuitry to cause a defined state if both the inverting and non-inverting inputs are left open; in this case the Q output goes LOW, while the Q output goes HIGH. This feature makes the device ideal for twisted pair applications.

If both inverting and non-inverting inputs are at an equal potential of $>-2.5 \mathrm{~V}$, the receiver does not go to a defined state, but rather current-shares in normal differential amplifier fashion, producing output voltage levels midway between HIGH and LOW, or the device may even

## MC10E116 MC100E116

## QUINT DIFFERENTIAL LINE RECEIVER

 oscillate.

The device $V_{B B}$ output is intended for use as a reference voltage for single-ended reception of ECL signals to that device only. When using for this purpose, it is recommended that $\mathrm{V}_{\mathrm{BB}}$ is decoupled to $\mathrm{V}_{\mathrm{CC}}$ via a $0.01 \mu \mathrm{~F}$ capacitor. Please refer to the interface section of the design guide for information on using the E116 in specialized applications.

The E116 features input pull-down resistors, as does the rest of the ECLinPS family. For applications which require bandwidths greater than that of the E116, the E416 device may be of interest.

1. Within-device skew is defined as identical transitions on similar paths through a device.

## 4-Bit D Flip-Flop

The MC10E/100E131 is a quad master-slave D-type flip-flop with differential outputs. Each flip-flop may be clocked separately by holding Common Clock ( $\mathrm{C}_{\mathrm{C}}$ ) LOW and using the Clock Enable (CE) inputs for clocking. Common clocking is achieved by holding the CE inputs LOW and using $\mathrm{C}_{\mathrm{C}}$ to clock all four flip-flops. In this case, the CE inputs perform the function of controlling the common clock, to each flip-flop.

Individual asynchronous resets are provided (R). Asynchronous set controls (S) are ganged together in pairs, with the pairing chosen to reflect physical chip symmetry.

Data enters the master when both $\mathrm{C}_{\mathrm{C}}$ and $\overline{\mathrm{CE}}$ are LOW, and transfers to the slave when either $\mathrm{C}_{\mathrm{C}}$ or CE (or both) go HIGH.

- 1100 MHz Min. Toggle Frequency
- Differential Outputs
- Individual and Common Clocks
- Individual Resets (asynchronous)
- Paired Sets (asynchronous)
- Extended 100E VEE Range of -4.2 V to -5.46 V
- $75 \mathrm{k} \Omega$ Input Pulldown Resistors

* All $\mathrm{V}_{\mathrm{CC}}$ and $\mathrm{V}_{\mathrm{CCO}}$ pins are tied together on the die.

## PIN NAMES

| Pin | $\quad$ Function |
| :--- | :--- |
| $\underline{D_{0}-D_{3}}$ |  |
| $C E_{0}-C E_{3}$ | Data Inputs |
| $R_{0}-R_{3}$ | Clock Enables (Individual) |
| $C_{C}$ | Resets |
| $S_{03}, S_{12}$ | Common Clock |
| $Q_{0}-Q_{3}$ | Sets (paired) |
| $Q_{0}-Q_{3}$ | True Outputs |

1. Setup/hold times guaranteed for both $\mathrm{C}_{\mathrm{C}}$ and CE .
2. Within-device skew is defined as identical transitions on similar paths through a device.

## 6-Bit Universal Up/Down Counter

The MC10E/100E136 is a 6-bit synchronous, presettable, cascadable universal counter. The device generates a look-ahead-carry output and accepts a look-ahead-carry input. These two features allow for the cacading of multiple E136's for wider bit width counters that operate at very nearly the same frequency as the stand alone counter.

- 550 MHz Count Frequency
- Fully Synchronous Up and Down Counting
- Internal $75 \mathrm{k} \Omega$ Input Pulldown Resistors
- Look-Ahead-Carry Input and Output
- Asynchronous Master Reset
- Extended 100E VEE Range of -4.2 V to -5.46 V

The CLOUT output will pulse LOW for one clock cycle one count before the E136 reaches terminal count. The COUT output will pulse LOW for one clock cycle when the counter reaches terminal count. For more information on utilizing the look-ahead-carry features of the device please refer to the applications section of this data sheet. The differential COUT output facilitates the E136's use in programmable divider and self-stopping counter applications.

Unlike the H136 and other similar universal counter designs the E136 carry out and look-ahead-carry out signals are registered on chip. This design alleviates the glitch problem seen on many counters where the carry out signals are merely gated. Because of this architecture there are some minor functional differences between the E136 and H136 counters. The user, regardless of familiarity with the H136, should read this data sheet carefully. Note specifically (see logic diagram) the operation of the carry out outputs and the look-ahead-carry in input when utilizing the master reset.

When left open all of the input pins will be pulled LOW via an input pulldown resistor. The master reset is an asynchronous signal which when asserted will force the Q outputs LOW.

The Q outputs need not be terminated for the E136 to function properly, in fact if these outputs will not be used in a system it is recommended to save power and minimize noise that they be left open. This practice will minimize switching noise which can reduce the maximum count frequency of the device or significantly reduce margins against other noise in the system.

PIN NAMES

| Pin | $\quad$ Function |
| :--- | :--- |
| $\mathrm{D}_{0}-\mathrm{D}_{5}$ | Preset Data Inputs |

Z = Low to High Transition

## APPLICATIONS INFORMATION

## Overview

The MC10E/100E136 is a 6-bit synchronous, presettable, cascadable universal counter. Using the S1 and S2 control pins the user can select between preset, count up, count down and hold count. The master reset pin will reset the internal counter, and set the COUT, CLOUT, and CLIN flip-flops. Unlike previous 136 type counters the carry out outputs will go to a high state during the preset operation. In addition since the carry out outputs are registered they will not go low if terminal count is loaded into the register. The look-ahead-carry out output functions similarly.

Note from the schematic the use of the master information from the least significant bits for control of the two carry out functions. This architecture not only reduces the carry out delay, but is essential to incorporate the registered carry out functions. In addition to being faster, because these functions are registered the resulting carry out signals are stable and glitch free.

## Cascading Multiple E136 Devices

Many applications require counters significantly larger than the 6 bits available with the E136. For these applications several E136 devices can be cascaded to increase the bit width of the counter to meet the needs of the application.

In the past cascading several 136 type universal counters necessarily impacted the maximum count frequency of the resulting counter chain. This performance impact was the
result of the terminal count signal of the lower order counters having to ripple through the entire counter chain. As a result past counters of this type were not widely used in large bit counter applications.

An alternative counter architecture similar to the E016 binary counter was implemented to alleviate the need to ripple propagate the terminal count signal. Unfortunately these types of counters require external gating for cascading designs of more than two devices. In addition to requiring additional components, these external gates limit the cascaded count frequency to a value less than the free running count frequency of a single counter. Although there is a performance impact with this type of architecture it is minor compared to the impact of the ripple propagate designs. As a result the E016 type counters have been used extensively in applications requiring very high speed, wide bit width synchronous counters.

Motorola has incorporated several improvements to past universal counter designs in the E136 universal counter. These enhancements make the E136 the unparalleled leader in its class. With the addition of look-ahead-carry features on the terminal count signal, very large counter chains can be designed which function at very nearly the same clock frequency as a single free running device. More importantly these counter chains require no external gating. Figure 1 below illustrates the interconnect scheme for using the look-ahead-carry features of the E136 counter.

Figure 1. 24-bit Cascaded E136 Counter

Figure 2. Look-Ahead-Carry Input Structure
Note from the waveforms that the look-ahead-carry output (CLOUT) pulses low one clock pulse before the counter reaches terminal count. Also note that both CLOUT and the carry out pin (COUT) of the device pulse low for only one clock period. The input structure for look-ahead-carry in (CLIN) and carry in (CIN) is pictured in Figure 2.

The CLIN input is registered and then ORed with the $\overline{\mathrm{CIN}}$ input. From the truth table one can see that both the CIN and the CLIN inputs must be in a LOW state for the E136 to be enabled to count (either count up or count down). The CLIN inputs are driven by the CLOUT output of the lowest order E136 and therefore are only asserted for a single clock period. Since the CLIN input is registered it must be asserted one clock period prior to the CIN input.

If the counter previous to a given counter is at terminal count its COUT output and thus the CIN input of the given counter will be in the "LOW" state. This signals the given counter that it will need to count one upon the next terminal count of the least significant counter (LSC). The CLOUT output of the LSC will pulse low one clock period before it reaches terminal count. This CLOUT signal will be clocked into the CLIN input of the higher order counters on the following positive clock transition. Since both CIN and CLIN are in the LOW state the next clock pulse will cause the least significant counter to roll over and all higher order counters, if signaled by their CIN inputs, to count by one.

Figure 3. 6-bit Programmable Divider

During the clock pulse in which the higher order counter is counting by one the CLIN is clocking in the high signal presented by the CLOUT of the LSC. The CIN's in the higher order counter will ripple propagate through the chain to update the count status for the next occurrence of terminal count on the LSC. This ripple propagation will not affect the count frequency as it has $2^{6}-1$ or 63 clock pulses to ripple through without affecting the count operation of the chain.

The only limiting factor which could reduce the count frequency of the chain as compared to a free running single device will be the setup time of the CLIN input. This limit will consist of the CLK to CLOUT delay of the E136 plus the CLIN setup time plus any path length differences between the CLOUT output and the clock.

## Programmable Divider

Using external feedback of the COUT pin, the E136 can be configured as a programmable divider. Figure 3 illustrates the configuration for a 6 -bit count down programmable divider. If for some reason a count up divider is preferred the COUT signal is simply fed back to S 2 rather than S 1 . Examination of the truth table for the E136 shows that when both S1 and S2 are LOW the counter will parallel load on the next positive transition of the clock. If the S2 input is low and the S1 input is high the counter will be in the count down mode and will count towards an all zero state upon successive clock pulses. Knowing this and the operation of the COUT output it becomes a trivial matter to build programmable dividers.

For a programmable divider one wants to load a predesignated number into the counter and count to terminal count. Upon terminal count the counter should automatically reload the divide number. With the architecture shown in Figure 3 when the counter reaches terminal count the COUT output and thus the S1 input will go LOW, this combined with the low on S2 will cause the counter to load the inputs present on D0-D5. Upon loading the divide value into the counter COUT will go HIGH as the counter is no longer at terminal count thereby placing the counter back into the count mode.

Table 1. Preset Inputs Versus Divide Ratio

| Divide | Preset Data Inputs |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Ratio | D5 | D4 | D3 | D2 | D1 | D0 |
| 2 | L | L | L | L | L | H |
| 3 | L | L | L | L | H | L |
| 4 | L | L | L | L | H | H |
| 5 | L | L | L | H | L | L |

| $\bullet$ | $\bullet$ | $\bullet$ | $\bullet$ | $\bullet$ | $\bullet$ | $\bullet$ |
| 36 | H | L | L | L | H | H |
| 37 | H | L | L | H | L | L |
| 38 | H | L | L | H | L | H |
| $\bullet$ | $\bullet$ | $\bullet$ | $\bullet$ | $\bullet$ | $\bullet$ | $\bullet$ |
| $\bullet$ | $\bullet$ | $\bullet$ | $\bullet$ | $\bullet$ | $\bullet$ | $\bullet$ |
| 62 | H | H | H | H | L | H |
| 63 | H | H | H | H | H | L |
| 64 | H | H | H | H | H | H |

Figure 4. Programmable Divider Waveforms

The exercise of building a programmable divider then becomes simply determining what value to load into the counter to accomplish the desired division. Since the load operation requires a clock pulse, to divide by $\mathrm{N}, \mathrm{N}-1$ must be loaded into the counter. A single E136 device is capable of divide ratios of 2 to 64 inclusive, Table 1 outlines the load values for the various divide ratios. Figure 4 presents the waveforms resulting from a divide by 37 operation. Note that the availability of the COUT complimentary output COUT allows the user to choose the polarity of the divide by output.

For single device programmable counters the E016 counter is probably a better choice than the E136. The E016 has an internal feedback to control the reloading of the counter, this not only simplifies board design but also will result in a faster maximum count frequency.

For programmable dividers of larger than 8 bits the
superiority of the E016 diminishes, and in fact for very wide dividers the E136 will provide the capability of a faster count frequency. This potential is a result of the cascading features mentioned previously in this document. Figure 5 shows the architecture of a 24-bit programmable divider implemented using E136 counters. Note the need for one external gate to control the loading of the entire counter chain. An ideal device for the external gating of this architecture would be the 4 -input OR function in the 8 -lead SOIC ECLinPS Lite ${ }^{\text {TM }}$ family. However the final decision as to what device to use for the external gating requires a balancing of performance needs, cost and available board space. Note that because of the need for external gating the maximum count frequency of a given sized programmable divider will be less than that of a single cascaded counter.

Figure 5. 24-bit Programmable Divider Architecture

## 8-Bit Ripple Counter

The MC10E/100E137 is a very high speed binary ripple counter. The two least significant bits were designed with very fast edge rates while the more significant bits maintain standard ECLinPSTM output edge rates. This allows the counter to operate at very high frequencies while maintaining a moderate power dissipation level.

- 1.8 GHz Minimum Count Frequency
- Differential Clock Input and Data Output Pins
- VBB Output for Single-Ended Use
- Internal $75 \mathrm{k} \Omega$ Input Pulldown Resistors
- Synchronous and Asynchronous Enable Pins
- Asynchronous Master Reset
- Extended 100E VEE Range of -4.2 V to -5.46 V

The device is ideally suited for multiple frequency clock generation as well as a counter in a high performance ATE time measurement board.

Both asynchronous and synchronous enables are available to maximize the device's flexibility for various applications. The asynchronous enable input, A_Start, when asserted enables the counter while overriding any synchronous enable signals. The E137 features XORed enable inputs, EN1 and EN2, which are synchronous to the CLK input. When only one synchronous enable is asserted the counter becomes disabled on the next CLK transition; all outputs remain in the previous state poised for the other synchronous enable or A_Start to be asserted to re-enable the counter. Asserting both synchronous enables causes the counter to become enabled on the next transition of the CLK. If EN1 (or EN2) and CLK edges are coincident, sufficient delay has been inserted in the CLK path (to compensate for the XOR gate delay and the internal D-flip flop setup time) to insure that the synchronous enable signal is clocked correctly, hence, the counter is disabled.

The E137 can also be driven single-endedly utilizing the $\mathrm{V}_{\mathrm{BB}}$ output supply as the voltage reference for the CLK input signal. If a single-ended signal is to be used the $V_{\mathrm{BB}}$ pin should be connected to the CLK input and bypassed to ground via a $0.01 \mu \mathrm{~F}$ capacitor. $\mathrm{V}_{\mathrm{BB}}$ can only source/sink 0.5 mA , therefore it should be used as a switching reference for the E137 only.

All input pins left open will be pulled LOW via an input pulldown resistor. Therefore, do not leave the differential CLK inputs open. Doing so causes the current source transistor of the input clock gate to become saturated, thus upsetting the internal bias regulators and jeopardizing the stability of the device.

The asynchronous Master Reset resets the counter to an all zero state upon assertion.

Pinout: 28-Lead PLCC (Top View)

* All $\mathrm{V}_{\mathrm{CC}}$ and $\mathrm{V}_{\mathrm{CCO}}$ pins are tied together on the die.

1. Minimum input swing for which AC parameters are guaranteed. Full DC ECL output swings will be generated with only 50 mV input swings.

## 8-Bit Shift Register

The MC10E/100E141 is an 8-bit full-function shift register. The E141 performs serial/parallel in and serial/parallel out, shifting in either direction. The eight inputs $D_{0}-D_{7}$ accept parallel input data, while DL/DR accept serial input data for left/right shifting. The Qn outputs do not need to be terminated for the shift operation to function. To minimize noise and power, any Q output not used should be left unterminated.

- 700MHz Min. Shift Frequency
- 8-Bit
- Full-Function, Bi-Directional
- Asynchronous Master Reset
- Pin-Compatible with E241
- Extended 100E VEE Range of -4.2 V to -5.46 V
- $75 \mathrm{k} \Omega$ Input Pulldown Resistors

The select pins, SELO and SEL1, select one of four modes of operation: Load, Hold, Shift Left, Shift Right, according to the Function Table.

Input data is accepted a set-up time before the positive clock edge. A HIGH on the Master Reset (MR) pin asynchronously resets all the registers to zero.

Pinout: 28-Lead PLCC (Top View)

* All $\mathrm{V}_{\mathrm{CC}}$ and $\mathrm{V}_{\mathrm{CCO}}$ pins are tied together on the die.

1. Within-device skew is defined as identical transitions on similar paths through a device.

## 9-Bit Shift Register

The MC10E/100E142 is a 9-bit shift register, designed with byte-parity applications in mind. The E142 performs serial/parallel in and serial/parallel out, shifting in one direction. The nine inputs D0-D8 accept parallel input data, while S-IN accepts serial input data. The Qn outputs do not need to be terminated for the shift operation to function. To minimize noise and power, any Q output not used should be left unterminated.

- 700MHz Min. Shift Frequency
- 9-Bit for Byte-Parity Applications
- Asynchronous Master Reset
- Dual Clocks
- Extended 100E VEE Range of -4.2 V to -5.46 V
- $75 \mathrm{k} \Omega$ Input Pulldown Resistors

The SEL (Select) input pin is used to switch between the two modes of operation - SHIFT and LOAD. The shift direction is from bit 0 to bit 8. Input data is accepted by the registers a set-up time before the positive going edge of CLK1 or CLK2; shifting is also accomplished on the positive clock edge. A HIGH on the Master Reset pin (MR) asynchronously resets all the resisters to zero.

* $\mathrm{All} \mathrm{V}_{\mathrm{CC}}$ and $\mathrm{V}_{\mathrm{CCO}}$ pins are tied together on the die.

PIN NAMES

| Pin |  | Function |

1. Within-device skew is defined as identical transitions on similar paths through a device.

## 9-Bit Hold Register

The MC10E/100E143 is a 9-bit holding register, designed with byte-parity applications in mind. The E143 holds current data or loads new data, with the nine inputs D0 - D8 accepting parallel input data.

- 700MHz Min. Operating Frequency
- 9-Bit for Byte-Parity Applications
- Asynchronous Master Reset
- Dual Clocks
- Extended 100E VEE Range of -4.2 V to -5.46 V
- $75 \mathrm{k} \Omega$ Input Pulldown Resistors

The SEL (Select) input pin is used to switch between the two modes of operation - HOLD and LOAD. Input data is accepted by the registers a set-up time before the positive going edge of CLK1 or CLK2. A HIGH on the Master Reset pin (MR) asynchronously resets all the registers to zero.

* All $\mathrm{V}_{\mathrm{CC}}$ and $\mathrm{V}_{\mathrm{CCO}}$ pins are tied together on the die.

PIN NAMES

| Pin |  | Function |
| :--- | :--- | :--- |
| $D_{0}-D_{8}$ | Parallel Data Inputs |  |
| SEL | Mode Select Input |  |
| CLK1, CLK2 | Clock Inputs |  |
| MR | Master Reset |  |
| $Q_{0}-Q_{8}$ | Data Outputs |  |
| NC | No Connection |  |

## 6-Bit D Latch

The MC10E/100E150 contains six D-type latches with differential outputs. When both Latch Enables (LEN1, LEN2) are LOW, the latch is transparent and input data transitions propagate through to the output. A logic HIGH on either LEN1 or LEN2 (or both) latches the data. The Master Reset (MR) overrides all other controls to set the $Q$ outputs low.

- 800ps Max. Propagation Delay
- Extended 100E VEE Range of -4.2 V to -5.46 V
- $75 \mathrm{k} \Omega$ Input Pulldown Resistors

LOGIC DIAGRAM

PIN NAMES

| Pin | $\quad$ Function |

## 6-Bit D Register

The MC10E/100E151 contains 6 D-type, edge-triggered, master-slave flip-flops with differential outputs. Data enters the master when both CLK1 and CLK2 are LOW, and is transferred to the slave when CLK1 or CLK2 (or both) go HIGH. The asynchronous Master Reset (MR) makes all Q outputs go LOW.

- 1100 MHz Min. Toggle Frequency
- Differential Outputs
- Asynchronous Master Reset
- Dual Clocks
- Extended 100E VEE Range of -4.2 V to -5.46 V
- $75 \mathrm{k} \Omega$ Input Pulldown Resistors

PIN NAMES

## 5-Bit 2:1 Mux-Latch

The MC10E/100E154 contains five 2:1 multiplexers followed by transparent latches with differential outputs. When both Latch Enables (LEN1, LEN2) are LOW, the latch is transparent, and output data is controlled by the multiplexer select control, SEL. A logic HIGH on either LEN1 or LEN2 (or both) latches the outputs. The Master Reset (MR) overrides all other controls to set the Q outputs LOW.

- 850ps Max. LEN to Output
- 825ps Max. D to Output
- Differential Outputs
- Asynchronous Master Reset
- Dual Latch-Enables
- Extended 100E VEE Range of -4.2 V to -5.46 V
- $75 \mathrm{k} \Omega$ Input Pulldown Resistors

* All $\mathrm{V}_{\mathrm{CC}}$ and $\mathrm{V}_{\mathrm{CCO}}$ pins are tied together on the die.

## PIN NAMES

1. Within-device skew is defined as identical transitions on similar paths through a device.

## 3-Bit 4:1 Mux-Latch

The MC10E/100E156 contains three $4: 1$ multiplexers followed by transparent latches with differential outputs. When both Latch Enables (LEN1, LEN2) are LOW, the latch is transparent, and output date is controlled by the multiplexer select controls (SELO, SEL1). A logic HIGH on either LEN1 or LEN2 (or both) latches the outputs. The Master Reset (MR) overrides all other controls to set the Q outputs LOW.

- 950ps Max. D to Output
- 850ps Max. LEN to Output
- Differential Outputs
- Asynchronous Master Reset
- Dual Latch-Enables
- Extended 100E VEE Range of -4.2 V to -5.46 V
- $75 \mathrm{k} \Omega$ Input Pulldown Resistors

* All $\mathrm{V}_{\mathrm{CC}}$ and $\mathrm{V}_{\mathrm{CCO}}$ pins are tied together on the die.

## 12-Bit Parity Generator/Checker

The MC10E/100E160 is a 12-bit parity generator/checker. The $Q$ output is HIGH when an odd number of inputs are HIGH. A HIGH on the Enable input (EN) forces the Q output LOW.

The E160 also features an output register. Multiplexers direct the register input, giving the option of holding present data by asserting HOLD LOW, or of shifting data in through the S-IN pin by asserting SHIFT HIGH. The output register itself is clocked by a positive edge on CLK1 or CLK2 (or both). A HIGH on the reset pin (R) overrides to force the Y output LOW.

- Provides Odd-HIGH Parity of 12 Inputs
- Shiftable Output Register with Hold
- 900ps Max. D to Q/Q Output
- Enable
- Asynchronous Register Reset
- Dual Clocks
- Extended 100E VEE Range of -4.2 V to -5.46 V
- $75 \mathrm{k} \Omega$ Input Pulldown Resistors

Pinout: 28-Lead PLCC (Top View)

* All $\mathrm{V}_{\mathrm{CC}}$ and $\mathrm{V}_{\mathrm{CCO}}$ pins are tied together on the die.

PIN NAMES

1. Within a device skew is guaranteed for identical transitions on similar paths through a device.

## 2-Bit 8:1 Multiplexer

The MC10E/100E163 contains two 8:1 multiplexers with differential outputs and common select inputs. The select inputs (SELO, 1, 2) control which one of the eight data inputs ( $A_{0}-A_{7}, B_{0}-B_{7}$ ) is propagated to the output.

- 850ps Max. D to Output
- Differential Outputs
- Extended 100E VEE Range of -4.2 V to -5.46 V
- $75 \mathrm{k} \Omega$ Input Pulldown Resistors

Pinout: 28-Lead PLCC (Top View)

${ }^{*}$ All $\mathrm{V}_{\mathrm{CC}}$ and $\mathrm{V}_{\mathrm{CCO}}$ pins are tied together on the die.

1. Within-device skew is defined as identical transitions on similar paths through a device; $n=0-7, m n, m=0-7$.

## 16:1 Multiplexer

The MC10E/100E164 is a $16: 1$ multiplexer with a differential output. The select inputs (SELO, 1, 2, 3) control which one of the sixteen data inputs ( $\mathrm{A} 0-\mathrm{A} 15$ ) is propagated to the output.

Special attention to the design layout results in a typical skew between the 16 inputs of only 50 ps.

- 850ps Data Input to Output
- Differential Output
- Extended 100E VEE Range of -4.2 V to -5.46 V
- Internal $75 \mathrm{k} \Omega$ Input Pulldown Resistors

Pinout: 28-Lead PLCC (Top View)

* All $\mathrm{V}_{\mathrm{CC}}$ and $\mathrm{V}_{\mathrm{CCO}}$ pins are tied together on the die.

## 6-Bit 2:1 Mux-Register

The MC10E/100E167 contains six 2:1 multiplexers followed by D flip-flops with single-ended outputs. Input data are selected by the Select control, SEL. The selected data are transferred to the flip-flop outputs by a positive edge on CLK1 or CLK2 (or both). A HIGH on the Master Reset (MR) pin asynchronously forces all Q outputs LOW.

- 1000 MHz Min. Operating Frequency
- 800ps Max. Clock to Output
- Single-Ended Outputs
- Asynchronous Master Resets
- Dual Clocks
- Extended 100E VEE Range of -4.2 V to -5.46 V
- $75 \mathrm{k} \Omega$ Input Pulldown Resistors

Pinout: 28-Lead PLCC (Top View)

* All $\mathrm{V}_{\mathrm{CC}}$ and $\mathrm{V}_{\mathrm{CCO}}$ pins are tied together on the die.

AC CHARACTERISTICS $\left(\mathrm{V}_{\mathrm{EE}}=\mathrm{V}_{\mathrm{EE}}(\right.$ min $)$ to $\left.\mathrm{V}_{\mathrm{EE}}(\max ) ; \mathrm{V}_{\mathrm{CC}}=\mathrm{V}_{\mathrm{CCO}}=\mathrm{GND}\right)$

1. Within-device skew is defined as identical transitions on similar paths through a device; $n=0,1,2 \mathrm{~m}=\mathrm{a}, \mathrm{b}, \mathrm{c}, \mathrm{d}$.

## 9-Bit Latch With Parity

The MC10E/100E175 is a 9-bit latch. It also features a tenth latched output, ODDPAR, which is formed as the odd parity of the nine data inputs (ODDPAR is HIGH if an odd number of the inputs are HIGH).

The E175 can also be used to generate byte parity by using D8 as the parity-type select ( $\mathrm{L}=$ e even parity, $\mathrm{H}=$ odd parity), and using ODDPAR as the byte parity output.

The LEN pin latches the data when asserted with a logical high and makes the latch transparent when placed at a logic low level.

- 9-Bit Latch
- Parity Detection/Generation
- 800ps Max. D to Output
- Reset
- Extended 100E VEE Range of -4.2 V to -5.46 V
- Internal $75 \mathrm{k} \Omega$ Input Pulldown Resistors

Pinout: 28-Lead PLCC (Top View)

* All $\mathrm{V}_{\mathrm{CC}}$ and $\mathrm{V}_{\mathrm{CCO}}$ pins are tied together on the die.

## PIN NAMES

## Error Detection/Correction Circuit

The MC10E/100E193 is an error detection and correction (EDAC) circuit. Modified Hamming parity codes are generated on an 8 -bit word according to the pattern shown in the logic symbol. The P5 output gives the parity of the whole word. The word parity is also provided at the PGEN pin, after Odd/Even parity control and gating with the BPAR input. This output also feeds to a 1-bit shiftable register, for use as part of a scan ring.

Used in conjunction with 12-bit parity generators such as the E160, a SECDED (single error correction, double error detection) error system can be designed for a multiple of an 8-bit word.

- Hamming Code Generation
- 8-Bit Word, Expandable
- Provides Parity of Whole Word
- Scannable Parity Register
- Extended 100E VEE Range of -4.2 V to -5.46 V
- $75 \mathrm{k} \Omega$ Input Pulldown Resistors

## Programmable Delay Chip

The MC10E/100E195 is a programmable delay chip (PDC) designed primarily for clock de-skewing and timing adjustment. It provides variable delay of a differential ECL input transition.
The delay section consists of a chain of gates organized as shown in the logic symbol. The first two delay elements feature gates that have been modified to have delays 1.25 and 1.5 times the basic gate delay of approximately 80 ps . These two elements provide the E195 with a digitally-selectable resolution of approximately 20 ps . The required device delay is selected by the seven address inputs $D[0: 6]$, which are latched on chip by a high signal on the latch enable (LEN) control.

Because the delay programmability of the E195 is achieved by purely differential ECL gate delays the device will operate at frequencies of $>1.0$ GHz while maintaining over 600 mV of output swing.
The E195 thus offers very fine resolution, at very high frequencies, that is selectable entirely from a digital input allowing for very accurate system clock timing.

An eighth latched input, D7, is provided for cascading multiple PDC's for increased programmable range. The cascade logic allows full control of multiple PDC's, at the expense of only a single added line to the data bus for each additional PDC, without the need for any external gating.

- 2.0ns Worst Case Delay Range
- $\approx 20 \mathrm{ps} /$ Delay Step Resolution
- >1.0GHz Bandwidth
- On Chip Cascade Circuitry
- Extended 100E VEE Range of -4.2 to -5.46 V
- $75 \mathrm{~K} \Omega$ Input Pulldown Resistors

1. Duty cycle skew guaranteed only for differential operation measured from the cross point of the input to the cross point of the output.
2. This setup time defines the amount of time prior to the input signal the delay tap of the device must be set.
3. This setup time is the minimum time that EN must be asserted prior to the next transition of $\mathrm{IN} / \mathrm{IN}$ to prevent an output response greater than $\pm 75 \mathrm{mV}$ to that $\mathrm{IN} / \mathrm{IN}$ transition.
4. This hold time is the minimum time that $\overline{E N}$ must remain asserted after a negative going $\mathbb{I N}$ or positive going $\overline{\mathbb{N}}$ to prevent an output response greater than $\pm 75 \mathrm{mV}$ to that $\mathrm{IN} / \mathrm{IN}$ transition.
5. This release time is the minimum time that EN must be deasserted prior to the next $I N / I N$ transition to ensure an output response that meets the specified IN to Q propagation delay and transition times.
6. Specification limits represent the amount of delay added with the assertion of each individual delay control pin. The various combinations of asserted delay control inputs will typically realize DO resolution steps across the specified programmable range.
7. The linearity specification guarantees to which delay control input the programmable steps will be monotonic (i.e. increasing delay steps for increasing binary counts on the control inputs Dn). Typically the device will be monotonic to the DO input, however under worst case conditions and process variation, delays could decrease slightly with increasing binary counts when the D0 input is the LSB. With the D1 input as the LSB the device is guaranteed to be monotonic over all specified environmental conditions and process variation.
8. The jitter of the device is less than what can be measured without resorting to very tedious and specialized measurement techniques.

Figure 1. Cascading Interconnect Architecture

## Cascading Multiple E195's

To increase the programmable range of the E195 internal cascade circuitry has been included. This circuitry allows for the cascading of multiple E195's without the need for any external gating. Furthermore this capability requires only one more address line per added E195. Obviously cascading multiple PDC's will result in a larger programmable range however this increase is at the expense of a longer minimum delay.

Figure 1 illustrates the interconnect scheme for cascading two E195's. As can be seen, this scheme can easily be expanded for larger E195 chains. The D7 input of the E195 is the cascade control pin. With the interconnect scheme of Figure 1 when D7 is asserted it signals the need for a larger programmable range than is achievable with a single device.
An expansion of the latch section of the block diagram is pictured below. Use of this diagram will simplify the explanation of how the cascade circuitry works. When D7 of chip \#1 above is low the cascade output will also be low while the cascade bar output will be a logical high. In this condition the SET MIN pin of chip \#2 will be asserted and thus all of the latches of chip \#2 will be reset and the device will be set at its minimum delay. Since the RESET and SET inputs of the latches are overriding any changes on the A0-A6 address bus will not affect the operation of chip \#2.

Chip \#1 on the other hand will have both SET MIN and SET MAX de-asserted so that its delay will be controlled entirely by the address bus A0-A6. If the delay needed is greater than can be achieved with 31.75 gate delays (1111111 on the A0-A6 address bus) D7 will be asserted to signal the need to cascade the delay to the next E195 device. When D7 is asserted the SET MIN pin of chip \#2 will be de-asserted and the delay will be controlled by the A0-A6 address bus. Chip \#1 on the other hand will have its SET MAX pin asserted resulting in the device delay to be independent of the A0-A6 address bus.

When the SET MAX pin of chip \#1 is asserted the D0 and D1 latches will be reset while the rest of the latches will be set. In addition, to maintain monotonicity an additional gate delay is selected in the cascade circuitry. As a result when D7 of chip \#1 is asserted the delay increases from 31.75 gates to 32 gates. A 32 gate delay is the maximum delay setting for the E195.

To expand this cascading scheme to more devices one simply needs to connect the D7 input and CASCADE outputs of the current most significant E195 to the new most significant E195 in the same manner as pictured in Figure 1. The only addition to the logic is the increase of one line to the address bus for cascade control of the second PDC.

Figure 2. Expansion of the Latch Section of the E195 Block Diagram

## Programmable Delay Chip

The MC10E/100E196 is a programmable delay chip (PDC) designed primarily for very accurate differential ECL input edge placement applications.

The delay section consists of a chain of gates and a linear ramp delay adjust organized as shown in the logic symbol. The first two delay elements feature gates that have been modified to have delays 1.25 and 1.5 times the basic gate delay of approximately 80 ps . These two elements provide the E196 with a digitally-selectable resolution of approximately 20 ps . The required device delay is selected by the seven address inputs $D[0: 6]$, which are latched on chip by a high signal on the latch enable (LEN) control.

The FTUNE input takes an analog voltage and applies it to an internal linear ramp for reducing the 20 ps resolution still further. The FTUNE input is what differentiates the E196 from the E195.

An eighth latched input, D7, is provided for cascading multiple PDC's for increased programmable range. The cascade logic allows full control of multiple PDC's, at the expense of only a single added line to the data bus for each additional PDC, without the need for any external gating.

- 2.0ns Worst Case Delay Range
- $\approx 20 \mathrm{ps} /$ Delay Step Resolution
- Linear Input for Tighter Resolution
- >1.0GHz Bandwidth
- On Chip Cascade Circuitry
- Extended 100E VEE Range of -4.2 to -5.46 V
- $75 \mathrm{~K} \Omega$ Input Pulldown Resistors

1. Duty cycle skew guaranteed only for differential operation measured from the cross point of the input to the cross point of the output.
2. This setup time defines the amount of time prior to the input signal the delay tap of the device must be set.
3. This setup time is the minimum time that EN must be asserted prior to the next transition of IN/IN to prevent an output response greater than $\pm 75 \mathrm{mV}$ to that IN/IN transition.
4. This hold time is the minimum time that EN must remain asserted after a negative going IN or positive going IN to prevent an output response greater than $\pm 75 \mathrm{mV}$ to that $\mathrm{IN} / \mathrm{IN}$ transition.
5. This release time is the minimum time that EN must be deasserted prior to the next IN/IN transition to ensure an output response that meets the specified IN to Q propagation delay and transition times.
6. Specification limits represent the amount of delay added with the assertion of each individual delay control pin. The various combinations of asserted delay control inputs will typically realize D0 resolution steps across the specified programmable range.
7. The linearity specification guarantees to which delay control input the programmable steps will be monotonic (i.e. increasing delay steps for increasing binary counts on the control inputs Dn). Typically the device will be monotonic to the D0 input, however under worst case conditions and process variation, delays could decrease slightly with increasing binary counts when the D0 input is the LSB. With the D1 input as the LSB the device is guaranteed to be monotonic over all specified environmental conditions and process variation.
8. The jitter of the device is less than what can be measured without resorting to very tedious and specialized measurement techniques.

## ANALOG INPUT CHARACTERISTICS

Ftune $=\mathrm{V}_{\mathrm{CC}}$ to $\mathrm{V}_{\mathrm{EE}}$

## USING THE FTUNE ANALOG INPUT

The analog FTUNE pin on the E196 device is intended to enhance the 20 ps resolution capabilities of the fully digital E195. The level of resolution obtained is dependent on the number of increments applied to the appropriate range on the FTUNE pin.
To provide another level of resolution the FTUNE pin must be capable of adjusting the delay by greater than the 20 ps digital resolution. From the provided graphs one sees that this requirement is easily achieved as over the entire FTUNE voltage range a 100 ps delay can be achieved. This extra analog range ensures that the FTUNE pin will be capable even under worst case conditions of covering the digital resolution.Typically the analog input will be driven by an external DAC to provide a digital control with very fine analog output steps. The final resolution of the device will be dependent on the width of the DAC chosen.
To determine the voltage range necessary for the FTUNE input, the graphs provided should be used. As an example if a range of 40 ps is selected to cover worst case conditions and ensure coverage of the digital range, from the 100E196 graph a voltage range of -3.25 V to -4.0 V would be necessary on the FTUNE pin. Obviously there are numerous voltage ranges which can be used to cover a given delay range, users are given the flexibility to determine which one best fits their designs.

## Cascading Multiple E196's

To increase the programmable range of the E196 internal cascade circuitry has been included. This circuitry allows for the cascading of multiple E196's without the need for any external gating. Furthermore this capability requires only one more address line per added E196. Obviously cascading multiple PDC's will result in a larger programmable range, however, this increase is at the expense of a longer minimum delay.

Figure 1 illustrates the interconnect scheme for cascading two E196's. As can be seen, this scheme can easily be
expanded for larger E196 chains. The D7 input of the E196 is the cascade control pin. With the interconnect scheme of Figure 1 when D7 is asserted it signals the need for a larger programmable range than is achievable with a single device.
An expansion of the latch section of the block diagram is pictured below. Use of this diagram will simplify the explanation of how the cascade circuitry works. When D7 of chip \#1 above is low the cascade output will also be low while the cascade bar output will be a logical high. In this condition the SET MIN pin of chip \#2 will be asserted and thus all of the latches of chip \#2 will be reset and the device will be set at its minimum delay. Since the RESET and SET inputs of the latches are overriding any changes on the A0-A6 address bus will not affect the operation of chip \#2.

Chip \#1 on the other hand will have both SET MIN and SET MAX de-asserted so that its delay will be controlled entirely by the address bus A0-A6. If the delay needed is greater than can be achieved with 31.75 gate delays (1111111 on the A0-A6 address bus) D7 will be asserted to signal the need to cascade the delay to the next E196 device. When D7 is asserted the SET MIN pin of chip \#2 will be de-asserted and the delay will be controlled by the A0-A6 address bus. Chip \#1 on the other hand will have its SET MAX pin asserted resulting in the device delay to be independent of the A0-A6 address bus.
When the SET MAX pin of chip \#1 is asserted the D0 and D1 latches will be reset while the rest of the latches will be set. In addition, to maintain monotonicity an additional gate delay is selected in the cascade circuitry. As a result when D7 of chip $\# 1$ is asserted the delay increases from 31.75 gates to 32 gates. A 32 gate delay is the maximum delay setting for the E196.

When cascading multiple PDC's it will prove more cost effective to use a single E196 for the MSB of the chain while using E195 for the lower order bits. This is due to the fact that only one fine tune input is needed to further reduce the delay step resolution.

## Advance Information <br> Data Separator

The MC10E197 is an integrated data separator designed for use in high speed hard disk drive applications. With data rate capabilities of up to $50 \mathrm{Mb} / \mathrm{s}$ the device is ideally suited for today's and future state-of-the-art hard disk designs.

The E197 is typically driven by a pulse detector which reads the magnetic information from the storage disk and changes it into ECL pulses. The device is capable of operating on both 2:7 and 1:7 RLL coding schemes. Note that the E197 does not do any decoding but rather prepares the disk data for decoding by another device.

For applications with higher data rate needs, such as tape drive systems, the device accepts an external VCO. The frequency capability of the integrated VCO is the factor which limits the device to $50 \mathrm{Mb} / \mathrm{s}$.

A special anti-equivocation circuit has been employed to ensure timely lock-up when the arriving data and VCO edges are coincident.

Unlike the majority of the devices in the ECLinPS family, the E197 is available in only 10 H compatible ECL. The device is available in the standard 28-lead PLCC.

Since the E197 contains both analog and digital circuitry, separate supply and ground pins have been provided to minimize noise coupling inside the device. The device can operate on either standard negative ECL supplies or, as is more common, on positive voltage supplies.

- 2:7 and 1:7 RLL Format Compatible

SETUP AND HOLD TIMING DIAGRAMS

## APPLICATIONS INFORMATION General Operation

## Operation

The E197 is a phase-locked loop circuit consisting of an internal VCO, a Data Phase detector with associated acquisition circuitry, and a Phase/Frequency detector (Figure 1). In addition, an enable pin(ENVCO) is provided to disable the internal VCO and enable the external VCO input. Hence, the user has the option of supplying the VCO signal.
The E197 contains two phase detectors: a data phase detector for synchronizing to the non-periodic pulses in the read data stream during the data read mode of operation, and a phase/ frequency detector for frequency (and phase) locking to an external reference clock during the "idle" mode of operation. The read enable (RDEN) pin muxes between these two detectors.

## Data Read Mode

The data pins (RAWD) are enabled when the RDEN pin is placed at a logic high level, thus enabling the Data Phase detector (Figure1) and initiating the data read mode. In this mode, the loop is servoed by the timing information taken from the positive edges of the input data pulses. This phase detector samples positive edges from the RAWD signal and generates both a pump up and pump down pulse from any edge of the input data pulse. The leading edge of the pump up pulse is time modulated by the leading edge of the data signal, whereas the rising edge of the pump up pulse is generated synchronous to the VCO clock. The falling edge of the pump down pulse is synchronous to the falling edge of the VCO clock and the rising edge of the pump down signal is synchronous to the rising edge of the VCO clock. Since both edges of the VCO are used the internal clock a duty cycle of $50 \%$. This pulse width modulation technique is used to generate the servoing signal which drives the VCO. The pump down signal is a reference pulse which is included to provide an evenly balanced differential system, thereby allowing the synthesis of a VCO input control signal after appropriate signal processing by the loop filter.

By using suitable external filter circuitry, a control signal for input into the VCO can be generated by inverting the pump down signal, summing the inverted signal with the pump up signal and averaging the result. The polarity of this control signal is defined as zero when the data edges lead the clock by a half clock cycle. If the data edges are advanced with respect to the zero polarity data/VCO edge relationship, the control signal is defined to have a negative polarity; whereas if the VCO is advanced with respect to the zero polarity data/VCO edge relationship, the control signal is defined to have a positive polarity. If there is no data edge present at the RAWD input, the corresponding pump up and pump down outputs are not generated and the resulting control output is zero.

## Acquisition Circuitry

The acquisition circuitry is provided to assist the data phase detector in phase locking to the sync field that precedes the data. For the case in which lock-up is attempted when the data edges are coincident with the VCO edges, the pump down signal may enter an indeterminate state for an unacceptably long period due to the violation of internal set up and hold times. After an initial pump down pulse, the circuit blocks successive pump down pulses, and inserts extra pump up pulses, during portions of the sync field that are known to contain zeros. Thus, the data phase detector is forced to have a nonzero output during the lock-up period, and the restoring force ensures correction of the loop within an acceptable time. Hence, this circuitry provides a quasi-deterministic pump down output signal, under the condition of coincident data and VCO edges, allowing lock-up to occur with excessive delays.

The ACQ line is provided to disable (disable = HIGH) the acquisition circuit during the data portion of a sector block. Typically, this circuit is enabled at the beginning of the sync field by a one-shot timer to ensure a timely lock-up.
The TYPE line allows the choice between two sync field preamble types; transitions interspersed with two zeros between transitions. These types of sync fields are used with the $1: 7$ and $2: 7$ coding schemes, respectively.

## Idle Mode

In the absence of data or when the drive is writing to the disk, PLL servoing is accomplished by pulling the read enable line (RDEN) low and providing a reference clock via the REFCLK pins. The condition whereby RDEN is low selects the Phase/Frequency detector (Figure 1) and the 10E197 is said to be operating in the "idle mode". In order to function as a frequency detector the input waveform must be periodic. The pump up and pump down pulses from the Phase/Frequency detector will have the same frequency, phase and pulse width only when the two clocks that are being compared have their positive edges aligned and are of the same frequency.
As with the data phase detector, by using suitable external filter circuitry, a VCO input control signal can be generated by inverting the pump down signal, summing the inverted signal with the pump up signal and averaging the result. The polarity
of this control signal is defined as zero when all positive edges of both clocks are coincident. For the case in which the frequencies of the two clocks are the same but the clock edges of the reference clock are slightly advanced with respect to the VCO clock, the control clock is defined to have a positive polarity. A control signal with negative polarity occurs when the edges of the reference clock are delayed with respect to those of the VCO. If the frequencies of the two clocks are different, the clock with the most edges per unit time will initiate the most pulses and the polarity of the detector will reflect the frequency error. Thus, when the reference clock is high in frequency than the VCO clock the polarity of the control signal is positive; whereas a control signal with negative polarity occurs when the frequency of the reference clock is lower than the VCO clock.

# Phase-Lock Loop Theory 

## Introduction

Phase lock loop (PLL) circuits are fundamentally feedback systems used to synchronize the frequency of an oscillator to an incoming signal. In addition to frequency synchronization, the PLL circuitry is designed to minimize the phase difference between the system input and output signals. A block diagram of a feedback control system is shown in Figure 1.
where:
$\mathrm{A}(\mathrm{s})$ is the product of the feed-forward transfer functions.

Figure 1. Feedback System
$\beta(s)$ is the product of the feedback transfer functions.

The transfer function for this closed loop system is

$$
\frac{X_{0}(s)}{X_{i}(s)}=\frac{A(s)}{1+A(s) \beta(s)}
$$

Typically, phase lock loops are modeled as feedback systems connected in a unity feedback configuration ( $\beta(\mathrm{s})=1$ ) with a phase detector, a VCO (voltage controlled oscillator), and a loop filter in the feed-forward path, A(s). Figure 2 illustrates a phase lock loop as a feedback control system in block diagram form.

Figure 2. Phase Lock Loop Block Diagram

The closed loop transfer function is:

$$
\frac{X_{0}(s)}{X_{i}(s)}=\frac{K_{\phi} \frac{K_{0}}{s} F(s)}{1+K_{\phi} \frac{K_{0}}{s} F(s)}
$$

where:
$\mathrm{K}_{\phi}=$ the phase detector gain.
$\mathrm{K}_{\mathrm{O}}=$ the VCO gain. Since the VCO introduces a pole at the origin of the s-plane, $\mathrm{K}_{\mathrm{O}}$ is divided by s .
$F(s)=$ the transfer function of the loop filter.

The 10E197 is designed to implement the phase detector and VCO functions in a unity feedback loop, while allowing the user to select the desired filter function.

## Gain Constants

As mentioned, each of the three sections in the phase lock loop block diagram has an associated open loop gain constant. Further, the gain constant of the filter circuitry is composed of the product of three gain constants, one for each filter subsection. The open loop gain constant of the feed-forward path is given by

$$
\mathrm{K}_{\mathrm{Ol}}=\mathrm{K}_{\phi}{ }^{*} \mathrm{~K}_{\mathrm{o}}{ }^{*} \mathrm{~K}_{1}{ }^{*} \mathrm{~K}_{\mathrm{l}}^{*} \mathrm{~K}_{\mathrm{d}}
$$

eqt. 1
and obtained by performing a root locus analysis.

## Phase Detector Gain Constant

The gain of the phase detector is a function of the operating mode and the data pattern. The 10E197 provides data
separation for signals encoded in 2:7 or 1:7 RLL encoding schemes; hence, Tables 1 and 2 are coding tables for these schemes. Table 3 lists nominal phase detector gains for both 2:7 and 1:7 sync fields.

| NRZ Data Sequence | Code Sequence |
| :--- | :--- |
| 00 | 1000 |
| 01 | 0100 |
| 100 | 001000 |
| 101 | 100100 |
| 111 | 000100 |
| 1100 | 00001000 |
| 1101 | 00100100 |

Table 1. 2:7 RLL Encoding Table

| NRZ Data Sequence | Code Sequence |
| :--- | :--- |
| 00 | X01 |
| 01 | 010 |
| 10 | X00 |
| 1100 | 010001 |
| 1101 | X00000 |
| 1110 | X00001 |
| 1111 | 010000 |

An X in the leading bit of a code sequence is assigned the complement of the bit

Table 2. 1:7 RLL Encoding Table

| Sync Pattern | Read Mode | Idle Mode |
| :---: | :---: | :---: |
| $2: 7$ | $121 \mathrm{mV} /$ radian | $484 \mathrm{mV} /$ radian |
| $1: 7$ | $161 \mathrm{mV} / \mathrm{radian}$ | $483 \mathrm{mV} /$ radian |

Table 3. Phase Detector Gain Constants

## VCO Gain Constant

The gain of the VCO is a function of the tuning capacitor. For a value of 10 pF a nominal value of the gain, $\mathrm{K}_{\mathrm{O}}$, is 20MHz per volt.

## Filter Circuitry Gain Constant(s)

The open loop gain constant of the filter circuitry is given by:

$$
\begin{equation*}
\mathrm{K}_{\mathrm{fc}}=\mathrm{K}_{1}{ }^{*} \mathrm{~K}_{\mathrm{l}}{ }^{*} \mathrm{~K}_{\mathrm{d}} \tag{eqt. 2}
\end{equation*}
$$

The individual gain constants are defined in the appropriate subsections of this document.

## Loop Filter

The two major functions of the loop filter are to remove any noise or high frequency components present in the phase detector output signal and, more importantly, to control the characteristics which determine the dynamic response of the phase lock loop; i.e. capture range, loop bandwidth, capture time, and transient response.

Although a variety of loop filter configurations exist, this section will only describe a filter capable of performing the signal processing as described in the Data Read Mode and the Idle Mode sections. The loop filter consists of a differential summing amplifier cascaded with an augmenting integrator which drives the VCOIN input to the 10E197 through a resistor divider network (Figure 3).
The transfer function and the element values for the loop filter are derived by dividing the filter into three cascaded subsections: filter input, augmenting integrator, and the voltage divider network (Figure 4).

## Loop Filter Transfer Function

The open loop transfer function of the phase lock loop is the product of each individual filter subsection, as well as the phase detector and VCO. Thus, the open loop filter transfer function is:

$$
\mathrm{F}_{0}(\mathrm{~s})=\mathrm{K}_{\phi} * \frac{\mathrm{~K}_{0}}{\mathrm{~s}} * \mathrm{~F}_{1}(\mathrm{~s}) * \mathrm{~F}_{\mathrm{l}}(\mathrm{~s}) * \mathrm{~F}_{\mathrm{d}}(\mathrm{~s})
$$

where:

$$
\begin{aligned}
& \mathrm{F}_{1}(\mathrm{~s})=\mathrm{K}_{1} * \frac{1}{\left(\mathrm{~s}+\mathrm{p}_{1}\right)} * \frac{1}{\left[\mathrm{~s}^{2}+\left(2 \zeta \omega_{\mathrm{o} 1}\right) \mathrm{s}+\omega_{\mathrm{O} 1}^{2}\right]} \\
& \mathrm{F}_{\mathrm{l}}(\mathrm{~s})=\mathrm{K}_{\mathrm{l}} * \frac{1}{\mathrm{~s}} * \frac{(\mathrm{~s}+\mathrm{z})}{\left[\mathrm{s}^{2}+\left(2 \zeta \omega_{\mathrm{o} 2}\right) \mathrm{s}+\omega_{\mathrm{o} 2}^{2}\right]} \\
& \mathrm{F}_{\mathrm{d}}(\mathrm{~s})=\mathrm{K}_{\mathrm{d}} * \frac{1}{\left(\mathrm{~s}+\mathrm{p}_{2}\right)}
\end{aligned}
$$

Figure 3. Loop Filter Circuitry

Figure 4. Loop Filter Block Diagram
A root locus analysis is performed on the open loop transfer function to determine the final pole-zero locations and the open loop gain constant for the phase lock loop. Note that the open loop gain constant impacts the crossover frequency and that a lower frequency crossover point means a much more efficient filter. Once these positions and constants are determined the component values may be calculated.

Figure 5. Filter Input Sunsection

## Filter Input

The primary function of the filter input subsection is to convert the output of the phase detector into a single ended signal for subsequent processing by the integrator circuitry. This subsection consists of the 10E197 charge pump current sinks, two shunt capacitors, and a differential summing amplifier (Figure 5).
Hence, this portion of the filter circuit contributes a real pole and two complex poles to the overall loop transfer function $\mathrm{F}(\mathrm{s})$. Before these pole locations are selected, appropriate values for the current setting resistors (RSETUP and RSETDN) must be ascertained. The goal in choosing these resistor values is to maximize the gain of the filter input subsection while ensuring the charge pump output transistors operate in the active mode. The filter input gain is maximized for a charge pump current of 1.1 mA ; a value of $464 \Omega$ for both RSETUP and RSETDN yields a nominal charge pump current of 1.1 mA .

It should be noted that a dual bandwidth implementation of the phase lock loop may be achieved by modifying the current setting resistors such that an electronic switch enables one of two resistor configurations. Figure 6 shows
a circuit configuration capable of providing this dual bandwidth function. Analysis of the filter input circuitry yields the transfer function:

$$
F_{1}(s)=K_{1} * \frac{1}{\left(s+p_{1}\right)} * \frac{1}{\left[s^{2}+\left(2 \zeta \omega_{o 1}\right) s+\omega_{01}^{2}\right]}
$$

The gain constant is defined as:

$$
\begin{equation*}
\mathrm{K}_{1}=\mathrm{A}_{1} * \frac{1}{\mathrm{C}_{\mathrm{IN}}} \tag{eqt. 3}
\end{equation*}
$$

where:
$\mathrm{A}_{1}=$ op-amp gain constant for the selected pole positions.
$\mathrm{C}_{\mathrm{IN}}=$ phase detector shunt capacitor.
The real pole is a function of the input resistance to the op-amp and the shunt capacitors connected to the phase detector output. For stability the real pole must be placed beyond the unity gain frequency; hence, this pole is typically placed midway between the unity crossover and phase detector sampling frequency, which should be about ten times greater.

Figure 6. Dual Bandwidth Current Source Implementation

The second order pole set arises from the two pole model for an op-amp. The open loop gain and the first open loop pole for the op-amp are obtained from the data sheets. Typically, op-amp manufacturers do not provide information on the location of the second open loop pole; however, it can be approximated by measuring the roll off of the op-amp in the open loop configuration. The second pole is located where the gain begins to decrease at a rate of 40dB per decade. The inclusion of both poles in the differential summing amplifier transfer function becomes important when closing the feedback path around the op-amp because the poles migrate; and this migration must be accounted for to accurately determine the phase lock loop transient performance.

Typically the op-amp poles can be approximated by a pole pair occurring as a complex conjugate pair making an angle of $45^{\circ}$ to the real axis of the complex frequency plane. Two constraints on the selection of the op-amp pole pair are that
the poles lie beyond the crossover frequency and they are positioned for near unity gain operation. Performing a root locus analysis on the op-amp open loop configuration and adhering to the two constraints yields the pole positions contributed by the op-amp.

## Determination of Element Values

Since the difference amplifier is configured to operate as a differential summer the resistor values associated with the amplifier are of equal value. Further, the typical input resistance to the summing amplifier is $1 \mathrm{k} \Omega$; thus, the op-amp resistors are set at $1 \mathrm{k} \Omega$. Having set the input resistance to the op-amp and selected the position of the real pole, the value of the shunt capacitors is determined using the following relationship:

$$
\left|p_{1}\right|=\frac{1}{2 \pi R_{1} \mathrm{C}_{I N}}
$$

eqt. 4

## Augmenting Integrator

The augmenting integrator consists of an active filter with a lag-lead network in the feedback path (Figure 7).

Figure 7. Integrator Subsection
Analysis of this portion of the filter circuit yields the transfer function:

$$
F_{1}(s)=K_{l} * \frac{1}{s} * \frac{(s+z)}{\left[s^{2}+\left(2 \zeta \omega_{02}\right) s+\omega_{02}^{2}\right]}
$$

The gain constant is defined as:

$$
\begin{equation*}
\mathrm{K}_{\mathrm{I}}=\mathrm{A}_{I} * \frac{\mathrm{R}_{\mathrm{A}}}{\mathrm{R}_{\mathrm{IA}}} \tag{eqt. 5}
\end{equation*}
$$

where:

$$
\begin{aligned}
& A_{I}=\text { op-amp gain constant for selected pole positions. } \\
& R_{A}=\text { integrator feedback resistor. } \\
& R_{I A}=\text { integrator input resistor. }
\end{aligned}
$$

The integrator circuit introduces a zero, a pole at the origin, and a second order pole set as described by the two pole model for an op-amp. As in the case of the differential summing amplifier, we assume the op-amp pole pair occur as
a complex conjugate pair making an angle of $45^{\circ}$ to the real axis of the complex frequency plane; are positioned for near unity gain operation; and are located beyond the crossover frequency. Since both the summing and integrating op-amps are realized by the same type of op-amp (MC34182D), the open loop pole positions for both amplifiers will be the same.

Further, the loop transfer function contains two poles located at the origin, one introduced by the integrator and the other by the VCO; hence a zero is necessary to compensate for the phase shift produced by these poles and ensure loop stability. The op-amp will be stable if the crossover point occurs before the transfer function phase angle becomes $180^{\circ}$. The zero should be positioned much less than one decade before the unity gain frequency.
As in the case of the filter input circuitry, the poles and zero from this analysis will be used as open loop poles and a zero when performing the root locus analysis for the complete system.

## Determination of Element Values

The location of the zero is used to determine the element values for the augmenting integrator. The value of the capacitor, $\mathrm{C}_{\mathrm{A}}$, is selected to provide adequate charge storage when the loop is not sampling data. A value of $0.1 \mu \mathrm{~F}$ is sufficient for most applications; this value may be increased when the RDCLK frequency is much lower than 4 MHz . The value of $R_{A}$ is governed by:

$$
\begin{equation*}
|z|=\frac{1}{2 \pi R_{A} C_{A}} \tag{eqt. 6}
\end{equation*}
$$

For unity gain operation of the integrating op-amp the value of RIA is selected such that:

$$
R_{I A}=R_{A}
$$

$$
\text { eqt. } 7
$$

It should be noted that although the zero can be tuned by varying either $R_{A}$ or $C_{A}$, caution must be exercised when adjusting the zero by varying $C_{A}$ because the integrator gain is also a function of $\mathrm{C}_{\mathrm{A}}$. Further, the gain of the loop filter can be adjusted by changing the integrator input resistor RIA.

## Voltage Divider

The input range to the VCOIN input is from $1.3 \mathrm{~V}+\mathrm{V}_{\mathrm{EE}}$ to $2.6 \mathrm{~V}+\mathrm{V}_{\mathrm{EE}}$; hence, the output from the augmenting amplifier section must be attenuated to meet the VCOIN constraints. A simple voltage divider network provides the necessary attenuation (Figure 8).

Figure 8. Voltage Divider Subsection

In addition, a shunt filter capacitor connected between the VCOIN input pin and $V_{\text {EE }}$ provides the voltage divider subsection with a single time constant transfer function that adds a pole to the overall loop filter. The transfer function for the voltage divider network is:

$$
\mathrm{F}_{\mathrm{d}}(\mathrm{~s})=\mathrm{K}_{\mathrm{d}} * \frac{1}{\left(\mathrm{~s}+\mathrm{p}_{2}\right)}
$$

The gain constant, $\mathrm{K}_{\mathrm{d}}$, is defined as:

$$
\begin{equation*}
\mathrm{K}_{\mathrm{d}}=\frac{1}{\mathrm{R}_{\mathrm{V}} \mathrm{C}_{\mathrm{d}}} \tag{eqt. 9}
\end{equation*}
$$

The value of $\mathrm{K}_{\mathrm{d}}$ is easily extracted by rearranging Equation 1:

$$
\mathrm{K}_{\mathrm{d}}=\frac{\mathrm{K}_{\mathrm{ol}}}{\mathrm{~K}_{\phi}{ }^{*} \mathrm{~K}_{\mathrm{O}}{ }^{*} \mathrm{~K}_{1}{ }^{*} \mathrm{~K}_{\mathrm{I}}}
$$

eqt. 10

The gain constant $\mathrm{K}_{\mathrm{d}}$ is set such that the output from the integrator circuit is within the range $1.3 \mathrm{~V}+\mathrm{V}_{\mathrm{EE}}$ to $2.6 \mathrm{~V}+\mathrm{V}_{\mathrm{EE}}$.

The pole for the voltage divider network should be positioned an octave beyond that for the filter input.

## Determination of Element Values

Once the pole location and the gain constant $\mathrm{K}_{\mathrm{d}}$ are established the resistor values for the voltage divider network are determined using the design guidelines mentioned above and from the following relationship:

$$
\frac{K_{d}}{2 \pi\left|p_{2}\right|}=\frac{R_{0}}{R_{O}+R_{V}}
$$

Having determined the resistor values, the filter capacitor is calculated by rearranging Equation 9:

$$
C_{d}=\frac{1}{R_{V} K_{d}} \quad \text { eqt. 9a }
$$

Finally, a bias diode is included in the voltage divider network to provide temperature compensation. The finite resistance of this diode is neglected for these calculations.

## Calculations For a 2:7 Coding Scheme

## Introduction

The circuit component values are calculated for a 2:7 coding scheme employing a data rate of $23 \mathrm{Mbit} / \mathrm{sec}$. Since the number of bits is doubled when the data is encoded, the data clock is at half the frequency of the RDCLK signal. Thus, the operating frequency for these calculations is 46 MHz . Further, the pole and zero positions are a function of the data rate; hence, the component values derived by these calculations must be scaled if a different operating frequency is used. Finally, it should be noted that the values are optimized for settling time.
The analysis is divided into three parts: static pole positioning, dynamic pole positioning, and dynamic zero positioning. Dynamic poles and zeros are those which the designer may position, to yield the desired dynamic response, through the judicious choice of element values. Static poles are not directly controlled by the choice of component values.

## Static Poles

Each op-amp introduces a pair of "static" complex conjugate poles which must lie beyond the crossover frequency. As obtained from the data sheets and laboratory measurements, the two open loop poles for the MC34182D are:

$$
\begin{aligned}
& \mathrm{P}^{*} 1 \mathrm{a}=-0.1 \mathrm{~Hz} \\
& \mathrm{P}^{*} 1 \mathrm{~b}=-11.2 \mathrm{~Hz}
\end{aligned}
$$

Performing a root locus analysis and following the two guidelines previously stated, an acceptable pole set is:

$$
\begin{aligned}
& P_{1 \mathrm{a}}=-5.65+j 5.65 \mathrm{MHz} \\
& P_{1 b}=-5.65-j 5.65 \mathrm{MHz}
\end{aligned}
$$

Both op-amps introduce a set of static complex conjugate poles at these positions for a total of four poles. Further, the loop gain for each op-amp associated with these pole positions is determined from the root locus analysis to be:

$$
\mathrm{A}_{1}=\mathrm{A}_{2}=2.48 \mathrm{e} 15 \frac{\mathrm{~V}}{\mathrm{~V}}
$$

In addition to the op-amps, the integrator and the VCO each contribute a static pole at the origin. Thus, there are a total of six static poles.

## Dynamic Poles

The filter input and the voltage divider sections each contribute a dynamic pole. As stated previously, the filter input pole should be positioned midway between the unity crossover point and the phase detector sampling frequency. Hence, the open loop filter input pole position is selected as:

$$
\mathrm{P}^{*} 1=-1.24 \mathrm{MHz}
$$

The voltage divider pole is set approximately one octave higher than the filter input pole. Thus the open loop voltage divider pole position is picked to be:

$$
P^{*} 2=-2.57 \mathrm{MHz}
$$

## Dynamic Zero

Finally, the zero is positioned much less than one decade before the crossover frequency; for this design the zero is placed at:

$$
\mathrm{z}=-311 \mathrm{~Hz}
$$

Once the dynamic pole and zero positions have been determined, the phase margin is determined using a Bode plot; if the phase margin is not sufficient, the dynamic poles may be moved to improve the phase margin. Finally, a root locus analysis is performed to obtain the optimum closed loop pole positions for the dynamic characteristics of interest.

## Component Values

Having determined the closed loop pole and zero positions the component values are calculated. From the root locus analysis the dynamic pole and zero positions are:

$$
\begin{aligned}
P_{1} & =-573 \mathrm{kHz} \\
P_{2} & =-3.06 \mathrm{MHz} \\
z & =-311 \mathrm{~Hz}
\end{aligned}
$$

## Filter Input Subsection

Rearranging Equation 4:

$$
\mathrm{C}_{\mathrm{IN}}=\frac{1}{2 \pi R_{1}\left|p_{1}\right|}
$$

and substituting 573 kHz for the pole position and $1 \mathrm{k} \Omega$ for the resistor value yields:

$$
\mathrm{C}_{\mathrm{IN}}=278 \mathrm{pF}
$$

## Augmenting Integrator Subsection

Rearranging Equation 6:

$$
R_{A}=\frac{1}{\substack{2 \pi|z| \\ C_{A}}}
$$

and substituting 311 Hz for the zero position and $0.1 \mu \mathrm{~F}$ for the capacitor value yields:

$$
\mathrm{R}_{\mathrm{A}}=5.11 \mathrm{k} \Omega
$$

From Equation 7 the value for the other resistors associated with the integrator op-amp are set equal to $R_{A}$ :

$$
\mathrm{R}_{\mathrm{IA}}=\mathrm{R}_{\mathrm{A}}=5.11 \mathrm{k} \Omega
$$

## Voltage Divider Subsection

The element values for the voltage divider network are calculated using the relationships presented in Equations 8, 9 , and 10 with the constraint that this divider network must produce a voltage that lies within the range $1.3 \mathrm{~V}+\mathrm{V}$ EE to 2.6 V $+V_{E E}$.
Restating Equation 9,

$$
\mathrm{K}_{\mathrm{d}}=\frac{\mathrm{K}_{\mathrm{Ol}}}{\mathrm{~K}_{\phi}{ }^{*} \mathrm{~K}_{\mathrm{O}}{ }^{*} \mathrm{~K}_{1}{ }^{*} \mathrm{~K}_{\mathrm{l}}}
$$

From the root locus analysis $\mathrm{K}_{\mathrm{Ol}}$ is determined to be:

$$
\mathrm{K}_{\mathrm{ol}}=1.585 \mathrm{e} 51 \frac{\mathrm{~V}}{\mathrm{~mA} \mathrm{sec}^{3}}
$$

From Equation 3

$$
\mathrm{K}_{1}=\mathrm{A}_{1} * \frac{1}{\mathrm{C}_{\mathrm{IN}}}
$$

and the gain constant $\mathrm{K}_{1}$ is:

$$
\mathrm{K}_{1}=8.90 \mathrm{e} 21 \frac{\mathrm{~V}}{\mathrm{~mA} \mathrm{sec}}
$$

From Equation 5

$$
K_{I}=A_{I} * \frac{R_{A}}{R_{I A}}
$$

and the gain constant $\mathrm{K}_{\mathrm{l}}$ is:

$$
\mathrm{K}_{\mathrm{I}}=2.48 \mathrm{e} 15 \frac{\mathrm{~V}}{\mathrm{~V}}
$$

Having determined the gain constant $K_{d}$, the value of $R_{V}$, is selected such that the constraints $R_{V}>R_{O}$ and:

$$
\frac{K_{d}}{2 \pi\left|p_{2}\right|}=\frac{R_{0}}{R_{0}+R_{v}}
$$

are fulfilled. The pole position $\mathrm{P}_{2}$ is determined from the root locus analysis to be:

$$
P_{2}=-3.06 \mathrm{MHz}
$$

Hence, $R_{V}$ is selected to be:

$$
\mathrm{R}_{\mathrm{V}}=2.15 \mathrm{k} \Omega
$$

and $R_{0}$ is calculated to be:

$$
\mathrm{R}_{\mathrm{O}}=700 \Omega
$$

Finally, using Equation 8a:

$$
C_{d}=\frac{1}{R_{V} K_{d}}
$$

the capacitor value, $\mathrm{C}_{\mathrm{d}}$ is:

$$
C_{d}=98 p F
$$

Note that the voltage divider section can be used to set the gain, but the designer is cautioned to be sure the input value to VCOIN is within the correct range.

## Component Scaling

As mentioned, these design equations were developed for a data rate of $23 \mathrm{Mbit} / \mathrm{sec}$. If the data rate is different from the nominal design value the reactive elements must be scaled accordingly. The following equations are provided to facilitate scaling and were derived with the assumptions that a 2:7 coding scheme is used and that the RDCLK signal is twice the frequency of the data clock.

$$
\begin{array}{lll}
C_{\text {IN }}=278 * \frac{46}{f} & (p F) & \text { eqt. } 11 \\
C_{d}=98 * \frac{46}{f} & (p F) & \text { eqt. } 12 \tag{pF}
\end{array}
$$

where f is the RDCLK frequency in MHz .

## Example for an $11 \mathrm{Mbit} / \mathrm{sec}$ Data Rate

As an example of scaling, assume the given filter and a 2:7 code are used but the data rate is $11 \mathrm{Mbit} / \mathrm{sec}$. The dynamic pole positions, and therefore the bandwidth of the loop filter, are a function of the data rate. Thus a slower data rate will force the dynamic poles and the bandwidth to move to a lower frequency. From Equation 11 the value of $\mathrm{C}_{\mathrm{IN}}$ is:

$$
\mathrm{C}_{\mathrm{IN}}=581 \mathrm{pF}
$$

and from Equation 12 the value of $\mathrm{C}_{\mathrm{d}}$ is:

$$
C_{d}=205 p F
$$

Thus the element values for the filter are:
Filter Input Subsection:

$$
\begin{aligned}
\mathrm{C}_{\mathrm{IN}} & =581 \mathrm{pF} \\
\mathrm{R}_{1} & =1 \mathrm{k} \Omega
\end{aligned}
$$

Integrator Subsection:

$$
\begin{aligned}
& \mathrm{C}_{\mathrm{A}}=0.1 \mu \mathrm{~F} \\
& \mathrm{R}_{\mathrm{A}}=5.11 \mathrm{k} \Omega \\
& \mathrm{R}_{\mathrm{IA}}=5.11 \mathrm{k} \Omega
\end{aligned}
$$

Voltage Divider Subsection:

$$
\begin{aligned}
& \mathrm{C}_{\mathrm{d}}=205 \mathrm{pF} \\
& \mathrm{R}_{\mathrm{V}}=2.15 \mathrm{k} \Omega \\
& \mathrm{R}_{\mathrm{O}}=700 \mathrm{k} \Omega
\end{aligned}
$$

Note, the poles $P_{1}$ and $P_{2}$ are now located at:

$$
\begin{aligned}
& P_{1}=-274 \mathrm{kHz} \\
& P_{2}=-1.47 \mathrm{MHz}
\end{aligned}
$$

And, the open loop filter unity crossover point is at 300 kHz . The gain can be adjusted by changing the value of $R_{I A}$ and the value of $\mathrm{C}_{d}$. Varying the gain by changing $\mathrm{C}_{\mathrm{d}}$ is not recommended because this will also move the poles, hence affect the dynamic 2 performance of the filter.

## Calculations For a 1:7 Coding Scheme

## Introduction

The circuit component values are calculated for a 1:7 coding scheme employing a data rate of $20 \mathrm{Mbit} / \mathrm{sec}$. Since the number of bits increases from two to three when the data is encoded, the data clock is at two-thirds the frequency of the RDCLK signal. Thus, the operating frequency for these calculations is 30 MHz . As in the case of the $2: 7$ coding scheme the pole and zero positions are a function of the data rate, hence the component values derived by these calculations must be scaled if a different operating frequency is used.
Again, the analysis is divided into three parts: static pole positioning, dynamic pole positioning, and dynamic zero positioning.

## Static Poles

As in the 2:7 coding example, an MC34182D op-amp is employed, hence the pole set is:

$$
\begin{aligned}
& P_{1 \mathrm{a}}=-5.65+j 5.65 \mathrm{MHz} \\
& P_{1 b}=-5.65-j 5.65 \mathrm{MHz}
\end{aligned}
$$

and the open loop gain is:

$$
\mathrm{A}_{\mathrm{l}}=\mathrm{A}_{2}=2.48 \mathrm{e} 15 \frac{\mathrm{~V}}{\mathrm{~V}}
$$

Since the op-amps introduce a set of complex conjugate poles, a total of four poles are introduced by the op-amp. In addition, the integrator and the VCO each contribute a pole at the origin for a total of six static poles.

## Dynamic Poles

The filter input and the voltage divider sections each contribute a dynamic pole. As stated previously, the filter input pole should be positioned midway between the unity crossover point and the phase detector sampling frequency. Hence, the open loop filter input pole position is selected as:

$$
\mathrm{P}^{*}{ }_{1}=-1.1 \mathrm{MHz}
$$

The voltage divider pole is set approximately one octave higher than the filter input pole. Thus, the open loop voltage divider pole position is selected as:

$$
\mathrm{P}^{*} 2=-2.28 \mathrm{MHz}
$$

## Dynamic Zero

Finally, the zero is positioned much less than one decade before the crossover frequency; for this design the zero is placed at:

$$
\mathrm{z}=-311 \mathrm{~Hz}
$$

Once the dynamic pole and zero positions have been determined, the phase margin is determined using a Bode plot; if the phase margin is not sufficient, the dynamic poles may be moved to improve the phase margin. Finally, a root locus analysis is performed to obtain the optimum closed loop pole positions for the dynamic characteristics of interest.

## Component Values

Having determined the closed loop pole and zero positions the component values are calculated. From the root locus analysis the dynamic pole and zero positions are:

$$
\begin{aligned}
P_{1} & =-541 \mathrm{kHz} \\
P_{2} & =-2.73 \mathrm{MHz} \\
z & =-311 \mathrm{~Hz}
\end{aligned}
$$

## Filter Input Subsection

Rearranging Equation 4

$$
\mathrm{C}_{\mathrm{IN}}=\frac{1}{2 \pi R_{1}\left|p_{1}\right|}
$$

and substituting 541 kHz for the pole position and $1.0 \mathrm{k} \Omega$ for the resistor value yields:

$$
\mathrm{C}_{\mathrm{IN}}=294 \mathrm{pF}
$$

## Augmenting Integrator Subsection

Rearranging Equation 6

$$
R_{A}=\frac{1}{2 \pi|z| C_{A}}
$$

and substituting 311 Hz for the zero position and $0.1 \mu \mathrm{~F}$ for the capacitor value yields:

$$
\mathrm{R}_{\mathrm{A}}=5.11 \mathrm{k} \Omega
$$

From Equation 7 the value for the other resistors associated with the integrator op-amp are set equal to $\mathrm{R}_{\mathrm{A}}$ :

$$
\mathrm{R}_{\mathrm{IA}}=\mathrm{R}_{\mathrm{A}}=5.11 \mathrm{k} \Omega
$$

## Voltage Divider Subsection

The element values for the voltage divider network are calculated using the relationships presented in Equations 8, 9 , and 10 with the constraint that this divider network must produce a voltage that lies within the range $1.3 \mathrm{~V}+\mathrm{V}_{\mathrm{EE}}$ to 2.6 V $+V_{E E}$.
Restating Equation 9,

$$
\mathrm{K}_{\mathrm{d}}=\frac{\mathrm{K}_{\mathrm{Ol}}}{\mathrm{~K}_{\phi}{ }^{*} \mathrm{~K}_{\mathrm{O}}{ }^{*} \mathrm{~K}_{1} * \mathrm{~K}_{\mathrm{I}}}
$$

From the root locus analysis $\mathrm{K}_{\mathrm{ol}}$ is determined to be:

$$
\mathrm{K}_{\mathrm{ol}}=1.258 \text { e } 51 \frac{\mathrm{~V}}{\mathrm{MA}} \underset{\mathrm{SEC}^{3}}{ }
$$

From Equation 3:

$$
\mathrm{K}_{1}=\mathrm{A}_{1} * \frac{1}{\mathrm{C}_{\mathrm{IN}}}
$$

and the gain constant $\mathrm{K}_{1}$ :

$$
\mathrm{K}_{1}=8.42 \mathrm{e} 21 \frac{\mathrm{~V}}{\mathrm{~mA} \mathrm{sec}}
$$

From Equation 5:

$$
\mathrm{K}_{I}=\mathrm{A}_{I} * \frac{\mathrm{R}_{\mathrm{A}}}{\mathrm{R}_{\mathrm{IA}}}
$$

and the gain constant $\mathrm{K}_{\mathrm{J}}$ is:

$$
\begin{aligned}
& \mathrm{K}_{\mathrm{I}}=2.48 \mathrm{e} 15 \frac{\mathrm{~V}}{\mathrm{~V}} \\
& \mathrm{~K}_{\mathrm{d}}=2.98 \mathrm{e} 6 \mathrm{sec}^{-1}
\end{aligned}
$$

Having determined the gain constant $K_{d}$, the value of $R_{V}$, is selected such that the constraints $R_{V}>R_{O}$ and:

$$
\frac{K_{d}}{2 \pi\left|p_{2}\right|}=\frac{R_{0}}{R_{0}+R_{V}}
$$

are fulfilled. The pole position $\mathrm{P}_{2}$ is determined from the root locus analysis to be:

$$
P_{2}=-2.73 \mathrm{MHz}
$$

Hence, $R_{V}$ is selected to be:

$$
\mathrm{R}_{\mathrm{V}}=2.15 \mathrm{k} \Omega
$$

and $R_{0}$ is calculated to be:

$$
\mathrm{R}_{\mathrm{O}}=453 \Omega
$$

Finally, using Equation 8a:

$$
C_{d}=\frac{1}{R_{V} K_{d}} \quad \text { eqt. 8a }
$$

the capacitor value, $\mathrm{C}_{\mathrm{d}}$ is calculated to be:

$$
C_{d}=156 p F
$$

Again, note the voltage divider section can be used to set the gain, but the designer is cautioned to be sure the input value to VCOIN is within the correct range.

## Component Scaling

As mentioned, these design equations were developed for a data rate of $20 \mathrm{Mbit} / \mathrm{sec}$. If the data rate is different from the nominal design value the reactive elements must be scaled accordingly. The following equations provided are to facilitate scaling and were derived with the assumptions that a $1: 7$ coding scheme is used and that the RDCLK signal is twice the frequency of the data clock:

$$
\begin{array}{lll}
C_{\text {IN }}=294 * \frac{30}{f} & (p F) & \text { eqt. } 13 \\
C_{d}=156 * \frac{30}{f} & (p F) & \text { eqt. } 14 \tag{pF}
\end{array}
$$

where f is the RDCLK frequency in MHz .

## Example for an $10 \mathrm{Mbit} / \mathrm{sec}$ Data Rate

As an example of scaling, assume the given filter and a 1:7 code are used but the data rate is $10 \mathrm{Mbit} / \mathrm{sec}$. The dynamic pole positions and, therefore, the bandwidth of the loop filter, are a function of the data rate. Thus, a slower data rate will force the dynamic poles and the bandwidth to move to a lower frequency. From Equation 13 the value of $\mathrm{C}_{\mathrm{IN}}$ is:

$$
\mathrm{C}_{\mathrm{IN}}=588 \mathrm{pF}
$$

and from Equation 14 the value of $C_{d}$ is:

$$
C_{d}=312 p F
$$

Thus, the element values for the filter are: Filter Input Subsection:

$$
\begin{aligned}
& \mathrm{C}_{\mathrm{IN}}=588 \mathrm{pF} \\
& \mathrm{R}_{1}=1.0 \mathrm{k} \Omega
\end{aligned}
$$

Integrator Subsection:
$C_{A}=0.1 \mu \mathrm{~F}$
$\mathrm{R}_{\mathrm{A}}=5.11 \mathrm{k} \Omega$
$R_{\mid A}=5.11 \mathrm{k} \Omega$

Voltage Divider Subsection:

$$
\begin{aligned}
& \mathrm{C}_{\mathrm{d}}=312 \mathrm{pF} \\
& \mathrm{R}_{\mathrm{V}}=2.15 \mathrm{k} \Omega \\
& \mathrm{R}_{\mathrm{O}}=453 \mathrm{k} \Omega
\end{aligned}
$$

Note, the poles $P_{1}$ and $P_{2}$ are now located at:

$$
\begin{aligned}
& P_{1}=-271 \mathrm{kHz} \\
& P_{2}=-1.36 \mathrm{MHz}
\end{aligned}
$$

And, the open loop filter unity crossover point is at 300 kHz .
As in the case of the 2:7 coding scheme, the gain can be adjusted by changing the value of $R_{I A}$ and the value of $C_{d}$. Varying the gain by changing $\mathrm{C}_{\mathrm{d}}$ is not recommended because this will also move the poles, hence affect the dynamic performance of the filter.

## Low Voltage Dual 1:4, $1: 5$ Differential Fanout Buffer ECL/PECL Compatible

For information on the MC100E210, please refer to the MC100LVE210 datasheet on page 4-11 in
Chapter 4 of this book.

## MC100E210

## 1:6 Differential Clock Distribution Chip

The MC10E/100E211 is a low skew 1:6 fanout device designed explicitly for low skew clock distribution applications. The device can be driven by either a differential or single-ended ECL or, if positive power supplies are used, PECL input signal (PECL is an acronym for Positive ECL, PECL levels are ECL levels referenced to +5 V rather than ground). If a single-ended input is to be used the $\mathrm{V}_{\mathrm{BB}}$ pin should be connected to the CLK input and bypassed to ground via a $0.01 \mu \mathrm{~F}$ capacitor. The $\mathrm{V}_{\mathrm{BB}}$ supply is designed to act as the switching reference for the input of the E211 under single-ended input conditions, as a result this pin can only source/sink up to 0.5 mA of current.

- Guaranteed Low Skew Specification
- Synchronous Enabling/Disabling
- Multiplexed Clock Inputs
- VBB Output for Single-Ended Use
- Internal $75 \mathrm{k} \Omega$ Input Pulldown Resistors
- Common and Individual Enable/Disable Control
- High Bandwidth Output Transistors
- Extended $100 \mathrm{E} \mathrm{V}_{\mathrm{EE}}$ Range of -4.2 V to -5.46 V

The E211 features a multiplexed clock input to allow for the distribution of a lower speed scan or test clock along with the high speed system clock. When LOW (or left open in which case it will be pulled LOW by the input pulldown resistor) the SEL pin will select the differential clock input.

## MC10E211 MC100E211

Both a common enable and individual output enables are provided. When asserted the positive output will go LOW on the next negative transition of the CLK (or SCLK) input. The enabling function is synchronous so that the outputs will only be enabled/disabled when the outputs are already in the LOW state. In this way the problem of runt pulse generation during the disable operation is avoided. Note that the internal flip flop is clocked on the falling edge of the input clock edge, therefore all associated specifications are referenced to the negative edge of the CLK input.

The output transitions of the E211 are faster than the standard ECLinPSTM edge rates. This feature provides a means of distributing higher frequency signals than capable with the E111 device. Because of these edge rates and the tight skew limits guaranteed in the specification, there are certain termination guidelines which must be followed. For more details on the recommended termination schemes please refer to the applications information section of this data sheet.

1. Within-Device skew is defined for identical transitions on similar paths through a device.
2. Setup, Hold and Disable times are all relative to a falling edge on CLK or SCLK.
3. Minimum input swing for which AC parameters are guaranteed. Full DC ECL output swings will be generated with only 50 mV input swings.
4. The range in which the high level of the input swing must fall while meeting the $\mathrm{V}_{\mathrm{PP}}$ spec. The lower end of the range is $\mathrm{V}_{\text {EE }}$ dependent and can be calculated as $V_{E E}+2.4 \mathrm{~V}$.

## APPLICATIONS INFORMATION

## General Description

The MC10E/100E211 is a 1:6 fanout tree designed explicitly for low skew high speed clock distribution. The device was targeted to work in conjunction with the E111 device to provide another level of flexibility in the design and implementation of clock distribution trees. The individual synchronous enable controls and multiplexed clock inputs make the device ideal as the first level distribution unit in a distribution tree. The device provides the ability to distribute a lower speed scan or test clock along with the high speed system clock to ease the design of system diagnostics and self test procedures. The individual enables could be used to allow for the disabling of individual cards on a backplane in fault tolerant designs.

Because of lower fanout and larger skews the E211 will not likely be used as an alternative to the E111 for the bulk of the clock fanout generation. Figure 1 shows a typical application combining the two devices to take advantage of the strengths of each.

Figure 1. Standard E211 Application

## Using the E211 in PECL Designs

The E211 device can be utilized very effectively in designs utilizing only a +5 V power supply. Since the internal switching reference levels are biased off of the $\mathrm{V}_{\mathrm{CC}}$ supply the input thresholds for the single-ended inputs will vary with $\mathrm{V}_{\mathrm{CC}}$. As a result the single-ended inputs should be driven by a device on the same board as the E211. Driving these inputs across a backplane where significant differences between the $\mathrm{V}_{\mathrm{CC}}$ 's of the transmitter and receiver can occur can lead to AC performance and/or significant noise margin degradations. Because the differential I/O does not use a switching reference, and due to the CMR range of the E211, even
under worst case $\mathrm{V}_{\mathrm{CC}}$ situations between cards there will be no AC performance or noise margin loss for the differential CLK inputs.

For situations where TTL clocks are required the E211 can be interfaced with the H641 or H643 ECL to TTL Clock Distribution Chips from Motorola. The H641 is a single supply 1:9 PECL to TTL device while the H643 is a $1: 8$ dual supply standard ECL to TTL device. By combining the superior skew performance of the E211, or E111, with the low skew translating capabilities of the H 641 and H 643 very low skew TTL clock distribution networks can be realized.

## Handling Open Inputs and Outputs

All of the input pins of the E211 have a $50 \mathrm{k} \Omega$ to $75 \mathrm{k} \Omega$ pulldown resistor to pull the input to $\mathrm{V}_{\text {EE }}$ when left open. This feature can cause a problem if the differential clock inputs are left open as the input gate current source transistor will become saturated. Under these conditions the outputs of the CLK input buffer will go to an undefined state. It is recommended, if possible,that the SCLK input should be selected any time the differential CLK inputs are allowed to float. The SCLK buffer, under open input conditions, will maintain a defined output state and thus the $Q$ outputs of the device will be in a defined state $(Q=L O W)$. Note that if all of the inputs are left open the differential CLK input will be selected and the state of the $Q$ outputs will be undefined.

With the simultaneous switching characteristics and the tight skew specifications of the E211 the handling of the unused outputs becomes critical. To minimize the noise generated on the die all outputs should be terminated in pairs, ie. both the true and compliment outputs should be terminated even if only one of the outputs will be used in the system. With both complimentary pairs terminated the current in the $\mathrm{V}_{\mathrm{CC}}$ pins will remain essentially constant and thus inductance induced voltage glitches on $\mathrm{V}_{\mathrm{CC}}$ will not occur. $\mathrm{V}_{\mathrm{CC}}$ glitches will result in distorted output waveforms and degradations in the skew performance of the device.

The package parasitics of the 28 -lead PLCC cause the signals on a given pin to be influenced by signals on adjacent pins. The E211 is characterized and tested with all of the outputs switching, therefore the numbers in the data book are guaranteed only for this situation. If all of the outputs of the E211 are not needed and there is a desire to save power the unused output pairs can be left unterminated. Unterminated outputs can influence the propagation delay on adjacent pins by 15 ps -20 ps. Therefore under these conditions this 15 ps 20ps needs to be added to the overall skew of the device. Pins which are separated by a package corner are not considered adjacent pins in the context of propagation delay influence. Therefore as long as all of the outputs on a single side of the package are terminated the specification limits in the data sheet will apply.

## APPLICATIONS INFORMATION

## Differential versus Single-Ended Use

As can be seen from the data sheet, to minimize the skew of the E211 the device must be used in the differential mode. In the single-ended mode the propagation delays are dependent on the relative position of the $\mathrm{V}_{\mathrm{BB}}$ switching reference. Any $\mathrm{V}_{\mathrm{BB}}$ offset from the center of the input swing will add delay to either the TPLH or TPHL and subtract delay from the other. This increase and decrease in delay will lead to an increase in the duty cycle skew and thus part-to-part skew. The within-device skew will be independent of the $V_{B B}$ and therefore will be the same regardless of whether the device is driven differentially or single-endedly.

For applications where part-to-part skew or duty cycle skew are not important the advantages of single-ended clock distribution may lead to its use. Using single-ended interconnect will reduce the number of signal traces to be routed, but remember that all of the complimentary outputs still need to be terminated therefore there will be no reduction in the termination components required. To use the E211 with a single-ended input the arrangement pictured in Figure 2b should be used. If the input to the differential CLK inputs are AC coupled as pictured in Figure 2a the dependence on a centered $\mathrm{V}_{\mathrm{BB}}$ reference is removed. The situation pictured will ensure that the input is centered around the bias set by the $V_{B B}$. As a result when AC coupled the AC specification limits for a differential input can be used. For more information on AC coupling please refer to the interfacing section of the design guide in the ECLinPS data book.

## Using the Enable Pins

Both the common enable (CEN) and the individual enables (ENx) are synchronous to the CLK or SCLK input depending on which is selected. The active low signals are clocked into the enable flip flops on the negative edges of the E211 clock inputs. In this way the devices will only be disabled when the outputs are already in the LOW state. The internal propagation delays are such that the delay to the output through the distribution buffers is less than that through the enable flip flops. This will ensure that the disabling of the device will not slice any time off the clock
pulse. On initial power up the enable flip flops will randomly attain a stable state, therefore precautions should be taken on initial power up to ensure the E211 is in the desired state.

Figure 2b. Single-Ended Input

## 3-Bit Scannable Registered Address Driver

The MC10E/100E212 is a scannable registered ECL driver typically used as a fan-out memory address driver for ECL cache driving. In a VLSI array based CPU design, use of the E212 allows the user to conserve array output cell functionality and also output pins.

The input shift register is designed with control logic which greatly facilitates its use in boundary scan applications.

- Scannable Version E112 Driver
- 1025ps Max. CLK to Output
- Dual Differential Outputs
- Master Reset
- Extended 100E VEE Range of -4.2 V to -5.46 V
- Internal $75 \mathrm{k} \Omega$ Input Pulldown Resistors

Pinout: 28-Lead PLCC (Top View)

* All $\mathrm{V}_{\mathrm{CC}}$ and $\mathrm{V}_{\mathrm{CCO}}$ pins are tied together on the die.

## 8-Bit Scannable Register

The MC10E/100E241 is an 8-bit shiftable register. Unlike a standard universal shift register such as the E141, the E241 features internal data feedback organized so that the SHIFT control overrides the HOLD/LOAD control. This enables the normal operations of HOLD and LOAD to be toggled with a single control line without the need for external gating. It also enables switching to scan mode with the single SHIFT control line.

The eight inputs $D_{0}-D_{7}$ accept parallel input data, while S-IN accepts serial input data when in shift mode. Data is accepted a set-up time before the positive-going edge of CLK; shifting is also accomplished on the positive clock edge. A HIGH on the Master Reset pin (MR) asynchronously resets all the registers to zero.

- SHIFT overrides HOLD/LOAD Control
- 1000ps Max. CLK to Q
- Asynchronous Master Reset
- Pin-Compatible with E141
- Extended 100E VEE Range of -4.2 V to -5.46 V
- $75 \mathrm{k} \Omega$ Input Pulldown Resistors

Pinout: 28-Lead PLCC (Top View)

* All $\mathrm{V}_{\mathrm{CC}}$ and $\mathrm{V}_{\mathrm{CCO}}$ pins are tied together on the die.

## PIN NAMES

| Pin | Function |
| :--- | :--- |
| $D_{0}-D_{7}$ | Parallel Date Inputs |
| S-IN | Serial Data Inputs |
| SEL0 | SHIFT Control |
| SEL1 | HOLD/LOAD Control |
| CLK | Clock |
| MR | Master Reset |
| $Q_{0}-Q_{7}$ | Data Outputs |

| 0 | 1 | X | Shift Data |
| 0 | 0 | 1 | Hold Data |
| 0 | 0 | 0 | Load Data |

## 3-Bit 4:1 Mux-Latch

The MC10E/100E256 contains three $4: 1$ multiplexers followed by transparent latches with differential outputs. Separate Select controls are provided for the leading 2:1 mux pairs (see logic symbol).

When the Latch Enable (LEN) is LOW, the latch is transparent, and output data is controlled by the multiplexer select controls. A logic HIGH on LEN latches the outputs. The Master Reset (MR) overrides all other controls to set the Q outputs LOW.

- 950ps Max. D to Output
- 850ps Max. LEN to Output
- Split Select
- Differential Outputs
- Extended 100E VEE Range of -4.2 V to -5.46 V
- $75 \mathrm{k} \Omega$ Input Pulldown Resistors

* All $\mathrm{V}_{\mathrm{CC}}$ and $\mathrm{V}_{\mathrm{CCO}}$ pins are tied together on the die.

PLASTIC PACKAGE CASE 776-02

## 3-Bit Registered Bus Transceiver

The MC10E/MC100E336 contains three bus transceivers with both transmit and receive registers. The bus outputs (BUSO-BUS2) are specified for driving a $25 \Omega$ bus; the receive outputs (Q0-Q2) are specified for $50 \Omega$. The bus outputs feature a normal HIGH level $(\mathrm{VOH})$ and a cutoff LOW level - when LOW, the outputs go to -2.0 V and the output emitter-follower is "off", presenting a high impedance to the bus. The bus outputs also feature edge slow-down capacitors.

- $25 \Omega$ Cutoff Bus Outputs
- $50 \Omega$ Receiver Outputs
- Transmit and Receive Registers
- 1500ps Max. Clock to Bus
- 1000ps Max. Clock to Q
- Bus Outputs Feature Internal Edge Slow-Down Capacitors
- Additional Package Ground Pins
- Extended 100E VEE Range of -4.2 V to -5.46 V
- $75 \mathrm{k} \Omega$ Input Pulldown Resistors

The Transmit Enable pins (TEN) control whether current data is held in the transmit register, or new data is loaded from the A/B inputs. A LOW on both of the Bus Enable inputs (BUSEN), when clocked through the register, disables the bus outputs to -2.0 V .

The receiver section clocks bus data into the receive registers, after gating with the Receive Enable (RXEN) input.

All registers are clocked by a positive transition of CLK1 or CLK2 (or both).

Additional leadframe grounding is provided through the Ground pins (GND) which should be connected to OV. The GND pins are not electrically connected to the chip.

## MC10E336 MC100E336

## 3-BIT REGISTERED BUS TRANSCEIVER

* All $\mathrm{V}_{\mathrm{CC}}$ and $\mathrm{V}_{\mathrm{CCO}}$ pins are tied together on the die.

## 3-Bit Scannable Registered Bus Transceiver

The MC10E/100E337 is a 3-bit registered bus transceiver with scan. The bus outputs (BUS0-BUS2) are specified for driving a $25 \Omega$ bus; the receive outputs (Q0 - Q2) are specified for $50 \Omega$. The bus outputs feature a normal HIGH level ( V OH ) and a cutoff LOW level - when LOW, the outputs go to -2.0 V and the output emitter-follower is "off", presenting a high impedance to the bus. The bus outputs also feature edge slow-down capacitors.

- Scannable Version of E336
- $25 \Omega$ Cutoff Bus Outputs
- $50 \Omega$ Receiver Outputs
- Scannable Registers
- Sync. and Async. Bus Enables
- Non-inverting Data Path
- 1500ps Max. Clock to Bus (Data Transmit)
- 1000ps Max. Clock to Q (Data Receive)
- Bus Outputs Feature Internal Edge Slow-Down Capacitors
- Additional Package Ground Pins
- Extended 100E VEE Range of -4.2 V to -5.46 V
- $75 \mathrm{k} \Omega$ Input Pulldown Resistors

## MC10E337 MC100E337

## 3-BIT SCANNABLE REGISTERED BUS TRANSCEIVER

Both drive and receive sides feature the same logic, including a loopback path to hold data. The HOLD/LOAD function is controlled by Transmit Enable (TEN) and Receive Enable (REN) on the transmit and receive sides respectively, with a HIGH selecting LOAD. Note that the implementation of the E337 Receive Enable differs from that of the E336.

A synchronous bus enable (SBUSEN) is provided for normal, non-scan operation. The asynchronous bus disable (ABUSDIS) disables the bus immediately for scan mode.

The $\overline{\text { SYNCEN }}$ input is provided for flexibility when re-enabling the bus after disabling with $\overline{\text { ABUSDIS, }}$, allowing either synchronous or asynchronous re-enabling. An alternative use is asynchronous-only operation with ABUSDIS, in which case SYNCEN is tied LOW, or left open. SYNCEN is implemented as an overriding SET control (active-LOW) to the enable flip-flop.

Scan mode is selected by a HIGH at the SCAN input. Scan input data is shifted in through S_IN and output data appears at the Q2 output.

All registers are clocked on the positive transition of CLK. Additional lead-frame grounding is provided through the Ground pins (GND) which should be connected to OV. The GND pins are not electrically connected to the chip.

## PIN NAMES

| Pin |  |
| :--- | :--- |
| $A_{0}-A_{2}$ | Data Inputs A |
| $B_{0}-B_{2}$ | Data Inputs B |
| S-IN | Serial (Scan) Data Input |
| TEN, REN | HOLD/LOAD Controls |
| SCAN | Scan Control |
| ABUSDIS | Asynchronous Bus Disable |
| SBUSEN | Synchronous Bus Enable |
| SYNCEN | Synchronous Enable Control |
| CLK | Clock |
| BUS0 - BUS2 | $25 \Omega$ Cutoff Bus Outputs |
| $Q_{0}-Q_{2}$ | Receive Data Outputs (Q2 serves as SCAN_OUT in scan mode) |

## Quad Differential AND/NAND

The MC10E404/100E404 is a 4-bit differential AND/NAND device. The differential operation of the device makes it ideal for pulse shaping applications where duty cycle skew is critical. Special design techniques were incorporated to minimize the skew between the upper and lower level gate inputs.

Because a negative 2-input NAND function is equivalent to a 2 -input OR function, the differential inputs and outputs of the device also allow for its use as a fully differential 2 input OR/NOR function.

The output RISE/FALL times of this device are significantly faster than most other standard ECLinPS devices resulting in an increased bandwidth.

The differential inputs have clamp structures which will force the Q output of a gate in an open input condition to go to a LOW state. Thus, inputs of unused gates can be left open and will not affect the operation of the rest of the device. Note that the input clamp will take affect only if both inputs fall 2.5 V below $\mathrm{V}_{\mathrm{CC}}$.

- Differential D and Q
- 700ps Max. Propagation Delay
- High Frequency Outputs
- Extended 100E VEE Range of -4.2 V to -5.46 V
- Internal $75 \mathrm{k} \Omega$ Input Pulldown Resistors

* All $\mathrm{V}_{\mathrm{CC}}$ and $\mathrm{V}_{\mathrm{CCO}}$ pins are tied together on the die.

1. Within-device skew is defined as identical transitions on similar paths through a device.
2. Minimum input swing for which AC parameters are guaranteed.

## 1:9 Differential ECL/PECL RAMBus Clock Buffer

The MC10E411 is a low skew 1-to-9 differential driver, designed with clock distribution in mind. The MC10E411's function and performance are similar to the popular MC10E111, with the added feature of 1.2 V output swings. It accepts one signal input, which can be either differential or single-ended if the $V_{\text {BB }}$ output is used. The signal is fanned out to 9 identical differential outputs.

- 200ps Part-to-Part Skew
- 50ps Output-to-Output Skew
- Differential Design
- VBB Output
- Voltage Compensated Outputs
- VEE Range of -4.5 to -5.5 V
- $75 \mathrm{k} \Omega$ Input Pulldown Resistors

The output voltage swing of the E411 is larger than a standard ECL swing. The 1.2 V output swings provide a signal which can be AC coupled into RAMBus compatible input loads. The larger output swings are produced by lowering the $\mathrm{V}_{\mathrm{OL}}$ of the device. With the exception of the lower VOL, the E411 is identical to the MC10E111. Note that the larger output swings eliminate the possibility of temperature compensated outputs, thus the E411 is only available in the 10E style of ECL. In addition, because the $\mathrm{V}_{\mathrm{OL}}$ is lower than standard ECL, the outputs cannot be terminated to -2.0 V . This datasheet provides a few termination alternatives.

The E411 is specifically designed, modeled and produced with low skew as the key goal. Optimal design and layout serve to minimize gate to gate skew within a device, and empirical modeling is used to determine process control limits that ensure consistent tpd distributions from lot to lot. The net result is a dependable, guaranteed low skew device.

## MC10E411

## 1:9 DIFFERENTIAL ECL/PECL RAMBUS CLOCK BUFFER

To ensure that the tight skew specification is met it is necessary that both sides of the differential output are terminated, even if only one side is being used. In most applications, all nine differential pairs will be used and therefore terminated. In the case where fewer than nine pairs are used, it is necessary to terminate at least the output pairs on the same package side as the pair(s) being used on that side, in order to maintain minimum skew. Failure to do this will result in small degradations of propagation delay (on the order of 10-20ps) of the output(s) being used which, while not being catastrophic to most designs, will mean a loss of skew margin.

The MC10E411, as with most other ECL devices, can be operated from a positive $\mathrm{V}_{\mathrm{CC}}$ supply in PECL mode. This allows the E411 to be used for high performance clock distribution in +5.0 V systems. Designers can take advantage of the E411's performance to distribute low skew clocks across the backplane or the board. In a PECL environment, series or Thevenin line terminations are typically used as they require no additional power supplies. For more information on using PECL, designers should refer to Motorola Application Note AN1406/D.

1. The differential propagation delay is defined as the delay from the crossing points of the differential input signals to the crossing point of the differential output signals.
2. The single-ended propagation delay is defined as the delay from the $50 \%$ point of the input signal to the $50 \%$ point of the output signal.
3. The setup time is the minimum time that EN must be asserted prior to the next transition of $\operatorname{IN} / \mathbb{I N}$ to prevent an output response greater than $\pm 75 \mathrm{mV}$ to that $\mathrm{IN} / \mathrm{IN}$ transition (see Figure 1).
4. The hold time is the minimum time that EN must remain asserted after a negative going IN or a positive going IN to prevent an output response greater than $\pm 75 \mathrm{mV}$ to that $\mathrm{IN} / \mathrm{IN}$ transition (see Figure 2).
5. The release time is the minimum time that EN must be deasserted prior to the next $I N / I N$ transition to ensure an output response that meets the specified $I N$ to Q propagation delay and output transition times (see Figure 3).
6. The within-device skew is defined as the worst case difference between any two similar delay paths within a single device.
7. $\mathrm{V}_{\mathrm{PP}}(\mathrm{min})$ is defined as the minimum input differential voltage which will cause no increase in the propagation delay. The $\mathrm{V}_{\mathrm{PP}}(\mathrm{min})$ is AC limited for the E411 as a differential input as low as 50 mV will still produce full ECL levels at the output.
8. $\mathrm{V}_{\mathrm{CMR}}$ is defined as the range within which the $\mathrm{V}_{\mathrm{IH}}$ level may vary, with the device still meeting the propagation delay specification. The $\mathrm{V}_{\mathrm{IL}}$ level must be such that the peak to peak voltage is less than 1.0 V and greater than or equal to $\mathrm{V}_{\mathrm{PP}}(\mathrm{min})$.

## Quint Differential Line Receiver

The MC10E416/100E416 is a 5 -bit differential line receiving device. The 2.0 GHz of bandwidth provided by the high frequency outputs makes the device ideal for buffering of very high speed oscillators.
$\mathrm{A} \bigvee_{\mathrm{BB}}$ pin is available to AC couple an input signal to the device. More information on $A C$ coupling can be found in the design handbook section of this data book.

The design incorporates two stages of gain, internal to the device, making it an excellent choice for use in high bandwidth amplifier applications.
The differential inputs have internal clamp structures which will force the Q output of a gate in an open input condition to go to a LOW state. Thus, inputs of unused gates can be left open and will not affect the operation of the rest of the device. Note that the input clamp will take affect only if both inputs fall 2.5 V below $\mathrm{V}_{\mathrm{CC}}$.

- Differential D and Q; VBB available
- 600ps Max. Propagation Delay
- High Frequency Outputs
- 2 Stages of Gain
- Extended 100E VEE Range of -4.2 V to -5.46 V
- Internal $75 \mathrm{k} \Omega$ Input Pulldown Resistors

* All $\mathrm{V}_{\mathrm{CC}}$ and $\mathrm{V}_{\mathrm{CCO}}$ pins are tied together on the die.

1. Within-device skew is defined as identical transitions on similar paths through a device.
2. Duty cycle skew defined only for differential operation when the delays are measured from the cross point of the inputs to the cross point of the outputs.
3. Minimum input swing for which AC parameters are guaranteed.

## 3-Bit Differential Flip-Flop

The MC10E/100E431 is a 3-bit flip-flop with differential clock, data input and data output.

The asynchronous Set and Reset controls are edge-triggered rather than level controlled. This allows the user to rapidly set or reset the flip-flop and then continue clocking at the next clock edge, without the necessity of de-asserting the set/reset signal (as would be the case with a level controlled set/reset).

The E431 is also designed with larger internal swings, an approach intended to minimize the time spent crossing the threshold region and thus reduce the metastability susceptibility window.

The differential input structures are clamped so that the inputs of unused registers can be left open without upsetting the bias network of the device. The clamping action will assert the D and the CLK sides of the inputs. Because of the edge triggered flip-flop nature of the device simultaneously opening both the clock and data inputs will result in an output which reaches an unidentified but valid state. Note that the input clamps only operate when both inputs fall to 2.5 V below $\mathrm{V}_{\mathrm{CC}}$.

- Edge-Triggered Asynchronous Set and Reset
- Differential D, CLK and Q; VBB Reference Available
- 1100 MHz Min. Toggle Frequency
- Extended 100E VEE Range of -4.2 V to -5.46 V

Pinout: 28-Lead PLCC (Top View)

* All $\mathrm{V}_{\mathrm{CC}}$ and $\mathrm{V}_{\mathrm{CCO}}$ pins are tied together on the die.

1. These setup times define the minimum time the CLK or SET/RESET input must wait after the assertion of the RESET/SET input to assure the proper operation of the flip-flop.
2. Within-device skew is defined as identical transitions on similar paths through a device.
3. Minimum input swing for which AC parameters are guaranteed.

## 4-Bit Serial/Parallel Converter

The MC10/100E445 is an integrated 4-bit serial to parallel data converter. The device is designed to operate for NRZ data rates of up to $2.0 \mathrm{~Gb} / \mathrm{s}$. The chip generates a divide by 4 and a divide by 8 clock for both 4 -bit conversion and a two chip 8 -bit conversion function. The conversion sequence was chosen to convert the first serial bit to $Q 0$, the second to Q1 etc.

- On-Chip Clock $\div 4$ and $\div 8$
- 2.0Gb/s Data Rate Capability
- Differential Clock and Serial Inputs
- VBB Output for Single-Ended Input Applications
- Asynchronous Data Synchronization
- Mode Select to Expand to 8-Bits
- Internal $75 \mathrm{k} \Omega$ Input Pulldown Resistors
- Extended 100 E VEE Range of -4.2 V to -5.46 V

Two selectable serial inputs provide a loopback capability for testing purposes when the device is used in conjunction with the E446 parallel to serial converter.

The start bit for conversion can be moved using the SYNC input. A single pulse applied asynchronously for at least two input clock cycles shifts the start bit for conversion from Qn to Qn-1. For each additional shift required an additional pulse must be applied to the SYNC input. Asserting the SYNC input will force the internal clock dividers to "swallow" a clock pulse, effectively shifting a bit from the Qn to the Qn-1 output (see
 Timing Diagram B).

The MODE input is used to select the conversion mode of the device. With the MODE input LOW, or open, the device will function as a 4-bit converter. When the mode input is driven HIGH the data on the output will change on every eighth clock cycle thus allowing for an 8 -bit conversion scheme using two E445's. When cascaded in an 8-bit conversion scheme the devices will not operate at the $2.0 \mathrm{~Gb} / \mathrm{s}$ data rate of a single device. Refer to the applications section of this data sheet for more information on cascading the E445.

For lower data rate applications a $V_{B B}$ reference voltage is supplied for single-ended inputs. When operating at clock rates above 500 MHz differential input signals are recommended. For single-ended inputs the $\mathrm{V}_{\mathrm{BB}}$ pin is tied to the inverting differential input and bypassed via a $0.01 \mu \mathrm{~F}$ capacitor. The $\mathrm{V}_{\mathrm{BB}}$ provides the switching reference for the input differential amplifier. The $\mathrm{V}_{\mathrm{BB}}$ can also be used to AC couple an input signal, for more information on AC coupling refer to the interfacing section of the design guide in the ECLinPS ${ }^{\text {TM }}$ data book.

Upon power-up the internal flip-flops will attain a random state. To synchronize multiple E445's in a system the master reset must be asserted.

TIMING DIAGRAMS

Timing Diagram A. 1:4 Serial to Parallel Conversion

Timing Diagram B. 1:4 Serial to Parallel Conversion With SYNC Pulse

## APPLICATIONS INFORMATION

The MC10E/100E445 is an integrated $1: 4$ serial to parallel converter. The chip is designed to work with the E446 device to provide both transmission and receiving of a high speed serial data path. The E445, can convert up to a $2.0 \mathrm{~Gb} / \mathrm{s}$ NRZ data stream into 4-bit parallel data. The device also provides a divide by four clock output to be used to synchronize the parallel data with the rest of the system.

The E445 features multiplexed dual serial inputs to provide test loop capability when used in conjunction with the E446. Figure 1 illustrates the loop test architecture. The architecture allows for the electrical testing of the link without requiring actual transmission over the serial data path medium. The SINA serial input of the E445 has an extra buffer delay and thus should be used as the loop back serial input.

Figure 1. Loopback Test Architecture

The E445 features a differential serial output and a divide by 8 clock output to facilitate the cascading of two devices to build a $1: 8$ demultiplexer. Figure 2 illustrates the architecture for a 1:8 demultiplexer using two E445's; the timing diagram for this configuration can be found on the following page. Notice the serial outputs (SOUT) of the lower order converter feed the serial inputs of the the higher order device. This feed through of the serial inputs bounds the upper end of the frequency of operation. The clock to serial output propagation delay plus the setup time of the serial input pins must fit into a single clock period for the cascade architecture to function properly. Using the worst case values for these two parameters from the data sheet, TPD CLK to SOUT = 1150ps and tS for $\mathrm{SIN}=-100 \mathrm{ps}$, yields a minimum period of 1050 ps or a clock frequency of 950 MHz .

The clock frequency is significantly lower than that of a single converter, to increase this frequency some games can be played with the clock input of the higher order E445. By delaying the clock feeding the second E445 relative to the clock of the first E445 the frequency of operation can be
increased. The delay between the two clocks can be increased until the minimum delay of clock to serial out would potentially cause a serial bit to be swallowed (Figure 3).

PARALLEL OUTPUT DATA

Figure 2. Cascaded 1:8 Converter Architecture

With a minimum delay of 800ps on this output the clock for the lower order E445 cannot be delayed more than 800ps relative to the clock of the first E445 without potentially missing a bit of information. Because the setup time on the serial input pin is negative coincident excursions on the data and clock inputs of the E445 will result in correct operation.

Figure 3. Cascade Frequency Limitation

Perhaps the easiest way to delay the second clock relative to the first is to take advantage of the differential clock inputs of the E445. By connecting the clock for the second E445 to the complimentary clock input pin the device will clock a half a clock period after the first E445 (Figure 4). Utilizing this simple technique will raise the potential conversion
frequency up to 1.4 GHz . The divide by eight clock of the second E445 should be used to synchronize the parallel data to the rest of the system as the parallel data of the two E445's will no longer be synchronized. This skew problem between the outputs can be worked around as the parallel information will be static for eight more clock pulses.

PARALLEL OUTPUT DATA
Figure 4. Extended Frequency 1:8 Demultiplexer

Timing Diagram A. 1:8 Serial to Parallel Conversion

## 4-Bit Parallel/Serial Converter

The MC10E/100E446 is an integrated 4-bit parallel to serial data converter. The device is designed to operate for NRZ data rates of up to $1.3 \mathrm{~Gb} / \mathrm{s}$. The chip generates a divide by 4 and a divide by 8 clock for both 4 -bit conversion and a two chip 8 -bit conversion function. The conversion sequence was chosen to convert the parallel data into a serial stream from bit D0 to D3. A serial input is provided to cascade two E446 devices for 8 bit conversion applications. Note that the serial output data clocks off of the negative input clock transition.

- On Chip Clock $\div 4$ and $\div 8$
- $1.5 \mathrm{~Gb} / \mathrm{s}$ Typical Data Rate Capability
- Differential Clock and Serial Inputs
- VBB Output for Single-ended Input Applications
- Asynchronous Data Synchronization
- Mode Select to Expand to 8 Bits
- Internal $75 \mathrm{k} \Omega$ Input Pulldown Resistors
- Extended 100E VEE Range of -4.2 V to -5.46 V

The SYNC input will asynchronously reset the internal clock circuitry. This pin allows the user to reset the internal clock conversion unit and thus select the start of the conversion process.

The MODE input is used to select the conversion mode of the device. With the MODE input LOW, or open, the device will function as a 4-bit converter. When the mode input is driven HIGH the internal load clock will change on every eighth clock cycle thus allowing for an 8 -bit conversion scheme using two E446's. When cascaded in an 8-bit conversion scheme the devices will not operate at the $1.3 \mathrm{~Gb} / \mathrm{s}$ data rate of a single device. Refer to the applications section of this data sheet for more information on cascading the E446.

For lower data rate applications a $V_{B B}$ reference voltage is supplied for single-ended inputs. When operating at clock rates above 500 MHz differential input signals are recommended. For single-ended inputs the $V_{B B}$ pin is tied to the inverting differential input and bypassed via a $0.01 \mu \mathrm{~F}$ capacitor. The $\mathrm{V}_{\mathrm{BB}}$ provides the switching reference for the input differential amplifier. The $\mathrm{V}_{\mathrm{BB}}$ can also be used to AC couple an input signal, for more information on AC coupling refer to the interfacing section of the design guide in the ECLinPSTM data book.

## PIN NAMES

Timing Diagrams

Timing Diagram A. 4:1 Parallel to Serial Conversion

## Applications Information

The MC10E/100E446 is an integrated 4:1 parallel to serial converter. The chip is designed to work with the E445 device to provide both transmission and receiving of a high speed serial data path. The E446 can convert 4 bits of data into a $1.3 \mathrm{~Gb} / \mathrm{s}$ NRZ data stream. The device features a SYNC input which allows the user to reset the internal clock circuitry and restart the conversion sequence (see timing diagram A).

The E446 features a differential serial input and internal divide by 8 circuitry to facilitate the cascading of two devices to build a 8:1 multiplexer. Figure 1 illustrates the architecture for a 8:1 multiplexer using two E446's; the timing diagram for this configuration can be found on the following page. Notice the serial outputs (SOUT) of the lower order converter feed the serial inputs of the the higher order device. This feed through of the serial inputs bounds the upper end of the frequency of operation. The clock to serial output propagation delay plus the setup time of the serial input pins must fit into a single clock period for the cascade architecture to function properly. Using the worst case values for these two parameters from the data sheet, TPD CLK to SOUT = 1480ps and tS for $\mathrm{SIN}=-200 \mathrm{ps}$, yields a minimum period of 1280 ps or a clock frequency of 780 MHz .

The clock frequency is somewhat lower than that of a single converter, to increase this frequency some games can be played with the clock input of the higher order E446. By delaying the clock feeding E446A relative to the clock of E446B the frequency of operation can be increased.

Figure 1. Cascaded 8:1 Converter Architecture

Timing Diagram B. 8:1 Parallel to Serial Conversion

## 6-Bit D Register Differential Data and Clock

The MC10E/100E451 contains six D-type flip-flops with single-ended outputs and differential data inputs. The common clock input is also differential. The registers are triggered by a positive transition of the positive clock (CLK) input.

A HIGH on the Master Reset (MR) input resets all Q outputs to LOW. The $\mathrm{V}_{\mathrm{BB}}$ output is intended for use as a reference voltage for single-ended reception of ECL signals to that device only. When using for this purpose, it is recommended that $\mathrm{V}_{\mathrm{BB}}$ is decoupled to $\mathrm{V}_{\mathrm{CC}}$ via a $0.01 \mu \mathrm{~F}$ capacitor.

The differential input structures are clamped so that the inputs of unused registers can be left open without upsetting the bias network of the device. The clamping action will assert the D and the CLK sides of the inputs. Because of the edge triggered flip-flop nature of the device simultaneously opening both the clock and data inputs will result in an output which reaches an unidentified but valid state. Note that the input clamps only operate when both inputs fall to 2.5 V below $\mathrm{V}_{\mathrm{CC}}$.

1. Minimum input voltage for which AC parameters are guaranteed.
2. Within-device skew is defined as identical transitions on similar paths through a device.

## 5-Bit Differential Register

The MC10E/100E452 is a 5-bit differential register with differential data (inputs and outputs) and clock. The registers are triggered by a positive transition of the positive clock (CLK) input. A high on the Master Reset (MR) asynchronously resets all registers so that the Q outputs go LOW.

The differential input structures are clamped so that the inputs of unused registers can be left open without upsetting the bias network of the device. The clamping action will assert the D and the CLK sides of the inputs. Because of the edge triggered flip-flop nature of the device simultaneously opening both the clock and data inputs will result in an output which reaches an unidentified but valid state. Note that the input clamps only operate when both inputs fall to 2.5 V below $\mathrm{V}_{\mathrm{CC}}$.

The fully differential design of the device makes it ideal for very high frequency applications where a registered data path is necessary.

- Differential D, CLK and Q; VBB Reference Available
- 1100 MHz Min. Toggle Frequency
- Asynchronous Master Reset
- Extended 100E VEE Range of -4.2 V to -5.46 V

Pinout: 28-Lead PLCC (Top View)

* All $\mathrm{V}_{\mathrm{CC}}$ and $\mathrm{V}_{\mathrm{CCO}}$ pins are tied together on the die.

## Triple Differential 2:1 Multiplexer

The MC10E457/100E457 is a 3-bit differential 2:1 multiplexer. The fully differential data path makes the device ideal for multiplexing low skew clock or other skew sensitive signals. Multiple VBB pins are provided to ease AC coupling input signals.

The higher frequency outputs provide the device with a $>1.0 \mathrm{GHz}$ bandwidth to meet the needs of the most demanding system clock.

Both, separate selects and a common select, are provided to make the device well suited for both data path and random logic applications.

The differential inputs have internal clamp structures which will force the Q output of a gate in an open input condition to go to a LOW state. Thus, inputs of unused gates can be left open and will not affect the operation of the rest of the device. Note that the input clamp will take affect only if both inputs fall 2.5 V below $\mathrm{V}_{\mathrm{CC}}$.

- Differential D and Q; VBB available
- 700ps Max. Propagation Delay
- High Frequency Outputs
- Separate and Common Select
- Extended $100 \mathrm{E} \mathrm{V}_{\mathrm{EE}}$ Range of -4.2 V to -5.46 V
- Internal $75 \mathrm{k} \Omega$ Input Pulldown Resistors

1. Within-device skew is defined as identical transitions on similar paths through a device.
2. Duty cycle skew is defined only for differential operation when the delays are measured from the cross point of the inputs to the cross point of the outputs.
3. Minimum input swing for which AC parameters are guaranteed.

## Dual ECL Output Comparator With Latch

The MC10E1651 is functionally and pin-for-pin compatible with the MC1651 in the MECL III family, but is fabricated using Motorola's advanced MOSAIC III process. The MC10E1651 incorporates a fixed level of input hysteresis as well as output compatibility with 10KH logic devices. In addition, a latch is available allowing a sample and hold function to be performed. The device is available in both a 16-pin DIP and a 20-pin surface mount package.

The latch enable ( $\overline{\mathrm{LEN}_{\mathrm{a}}}$ and $\left.\overline{\mathrm{LEN}} \mathrm{b}\right)$ input pins operate from standard ECL 10KH logic levels. When the latch enable is at a logic high level the MC10E1651 acts as a comparator, hence $Q$ will be at a logic high level if $\mathrm{V} 1>\mathrm{V} 2$ ( V 1 is more positive than V 2 ). Q is the complement of Q . When the latch enable input goes to a low logic level, the outputs are latched in their present state providing the latch enable setup and hold time constraints are met.

- Typ. 3.0 dB Bandwidth > 1.0 GHz
- Typ. V to Q Propagation Delay of 775 ps
- Typ. Output Rise/Fall of 350 ps
- Common Mode Range -2.0 V to +3.0 V
- Individual Latch Enables
- Differential Outputs
- 28mV Input Hysteresis

1. Hysteresis skew ( $\mathrm{V}_{\text {skew }}$ ) is provided to indicate the offset of the hysteresis window. For example, at $25^{\circ} \mathrm{C}$ the nominal hysteresis value is 27 mV and the $V_{\text {skew }}$ value indicates that the hysteresis was skewed from the reference level by 1 mV in the negative direction. Hence the hysteresis window ranged from 14 mV below the reference level to 13 mV above the reference level. All hysteresis measurements were determined using a reference voltage of 0 mV .

1. The propagation delay is measured from the crosspoint of the input signal and the threshold value to the crosspoint of the $Q$ and $Q$ output signals. For propagation delay measurements the threshold level ( V THR ) is centered about an 850 mV input logic swing with a slew rate of $0.75 \mathrm{~V} / \mathrm{NS}$. There is an insignificant change in the propagation delay over the input common mode range.
2. $t_{\text {skew }}$ is the propagation delay skew between comparator $A$ and comparator $B$ for a particular part under identical input conditions.
3. Refer to figure 4 and note that the input is at 850 mV ECL levels with the input threshold range between the $20 \%$ and $80 \%$ points. The delay is measured from the crosspoint of the input signal and the threshold value to the crosspoint of the Q and Q output signals
4. The slew rate is $0.25 \mathrm{~V} / \mathrm{NS}$ for input rising edges.
5. The slew rate is $0.75 \mathrm{~V} / \mathrm{NS}$ for input rising edges.
6. Refer to Figure 5 and note that the input is at 2.5 V TTL levels with the input threshold range between the $20 \%$ and $80 \%$ points. The delay is measured from the crosspoint of the input signal and the threshold value to the crosspoint of the $Q$ and $Q$ output signals.
7. The slew rate is $0.3 \mathrm{~V} / \mathrm{NS}$ for input rising edges.

## APPLICATIONS INFORMATION

The timing diagram (Figure 3) is presented to illustrate the MC10E1651's compare and latch features. When the signal on the LEN pin is at a logic high level, the device is operating in the "compare mode," and the signal on the input arrives at the output after a nominal propagation delay (tpHL, tpLH). The input signal must be asserted for a time, $\mathrm{t}_{\mathrm{s}}$, prior to the negative going transition on LEN and held for a time, $t_{h}$, after the LEN transition. After time th , the latch is operating in the "latch mode," thus transitions on the input do not appear at the output. The device continues to operate in the "latch mode" until the latch is asserted once again. Moreover, the LEN pulse must meet the minimum pulse width (tpw) requirement to effect the correct input-output relationship. Note that the LEN waveform in Figure 3 shows the LEN signal swinging around a reference labeled VBBINT; this waveform emphasizes the requirement that LEN follow typical ECL 10KH logic levels because VBBINT is the
internally generated reference level, hence is nominally at the ECL VBB level.

Finally, $\mathrm{V}_{\mathrm{OD}}$ is the input voltage overdrive and represents the voltage level beyond the threshold level ( $\mathrm{V}_{\mathrm{THR}}$ ) to which the input is driven. As an example, if the threshold level is set on one of the comparator inputs as 80 mV and the input signal swing on the complementary input is from zero to 100 mV , the positive going overdrive would be 20 mV and the negative going overdrive would be 80 mV . The result of differing overdrive levels is that the devices have shorter propagation delays with greater overdrive because the threshold level is crossed sooner than the case of lower overdrive levels. Typically, semiconductor manufactures refer to the threshold voltage as the input offset voltage (VOS) since the threshold voltage is the sum of the externally supplied reference voltage and inherent device offset voltage.

Figure 3. Input/Output Timing Diagram

## DELAY DISPERSION

Under a constant set of input conditions comparators have a specified nominal propagation delay. However, since propagation delay is a function of input slew rate and input voltage overdrive the delay dispersion parameters, TDE and TDT, are provided to allow the user to adjust for these variables (where TDE and TDT apply to inputs with standard ECL and TTL levels, respectively).

Figure 4 and Figure 5 define a range of input conditions which incorporate varying input slew rates and input voltage overdrive. For input parameters that adhere to these constraints the propagation delay can be described as:

TNOM $\pm$ TDE (or TDT)
where $\mathrm{T}_{\mathrm{NOM}}$ is the nominal propagation delay. $\mathrm{T}_{\mathrm{NOM}}$ accounts for nonuniformity introduced by temperature and voltage variability, whereas the delay dispersion parameter takes into consideration input slew rate and input voltage overdrive variability. Thus a modified propagation delay can be approximated to account for the effects of input conditions that differ from those under which the parts where tested. For example, an application may specify an ECL input with a slew rate of $0.25 \mathrm{~V} / \mathrm{NS}$, an overdrive of 17 mV and a temperature of $25^{\circ} \mathrm{C}$, the delay dispersion parameter would be 100 ps . The modified propagation delay would be

775ps $\pm 100$ ps

Figure 5. TTL Dispersion Test Input Conditions

## Dual ECL Output Comparator With Latch

The MC10E1652 is functionally and pin-for-pin compatible with the MC10E1651 and thus the MC1651 in the MECL IIITM family, but is fabricated using Motorola's advanced MOSAIC IIITM process and is output compatible with 10H logic devices. In addition, the device is available in both a 16-pin DIP and a 20 -pin surface mount package. However, the MC10E1652 provides user programmable hysteresis.

The latch enable ( $\overline{\mathrm{LEN}_{\mathrm{a}}}$ and $\left.\overline{\mathrm{LEN}} \mathrm{b}\right)$ input pins operate from standard ECL $10 \mathrm{H}^{\text {TM }}$ logic levels. When the latch enable is at a logic high level the MC10E1652 acts as a comparator, hence $Q$ will be at a logic high level if $\mathrm{V} 1>\mathrm{V} 2$ ( V 1 is more positive than V 2 ). Q is the complement of Q . When the latch enable input goes to a low logic level, the outputs are latched in their present state, providing the latch enable setup and hold time constraints are met. The level of input hysteresis is controlled by applying a bias voltage to the HYS pin.

- Typical 3.0 dB Bandwidth $>1.0 \mathrm{GHz}$
- Typical V to Q Propagation Delay of 775 ps
- Typical Output Rise/Fall of 350 ps
- Common Mode Range -2.0 V to +3.0 V
- Individual Latch Enables
- Differential Outputs
- Programmable Input Hysteresis

1. The HYS pin programming characterization information is shown in Figure 2, The hysteresis values indicated in the data sheet are for the condition in which the voltage on the HYS pin is set to $V_{E E}$.
2. Hysteresis skew ( $\mathrm{V}_{\text {skew }}$ ) is provided to indicate the offset of the hysteresis window. For example, at $25^{\circ} \mathrm{C}$ the nominal hysteresis value is 27 mV and the $\mathrm{V}_{\text {skew }}$ value indicates that the hysteresis was skewed from the reference level by 1 mV in the negative direction. Hence the hysteresis window ranged from 14 mV below the reference level to 13 mV above the reference level. All hysteresis measurements were determined using a reference voltage of 0 mV . The hysteresis skew values apply over the programming range shown in Figure 2.

7. The slew rate is $0.3 \mathrm{~V} / \mathrm{NS}$ for input rising edges.

## APPLICATIONS INFORMATION

The timing diagram (Figure 3) is presented to illustrate the MC10E1652's compare and latch features. When the signal on the LEN pin is at a logic high level, the device is operating in the "compare mode," and the signal on the input arrives at the output after a nominal propagation delay (tPHL, tPLH). The input signal must be asserted for a time, $\mathrm{t}_{\mathrm{s}}$, prior to the
negative going transition on LEN and held for a time, th, after the LEN transition. After time th, the latch is operating in the "latch mode," thus transitions on the input do not appear at the output. The device continues to operate in the "latch mode" until the latch is asserted once again. Moreover, the LEN pulse must meet the minimum pulse width (tpw)
requirement to effect the correct input-output relationship. Note that the LEN waveform in Figure 3 shows the LEN signal swinging around a reference labeled VBBINT; this waveform emphasizes the requirement that LEN follow typical ECL 10KH logic levels because VBBINT is the internally generated reference level, hence is nominally at the ECL VBB level.

Finally, $\mathrm{V}_{\mathrm{OD}}$ is the input voltage overdrive and represents the voltage level beyond the threshold level ( $\mathrm{V}_{\mathrm{THR}}$ ) to which the input is driven. As an example, if the threshold level is set on one of the comparator inputs as 80 mV and the input

Figure 3. Input/Output Timing Diagram

## DELAY DISPERSION

Under a constant set of input conditions comparators have a specified nominal propagation delay. However, since propagation delay is a function of input slew rate and input voltage overdrive the delay dispersion parameters, TDE and TDT, are provided to allow the user to adjust for these variables (where TDE and TDT apply to inputs with standard ECL and TTL levels, respectively).

Figure 4 and Figure 5 define a range of input conditions which incorporate varying input slew rates and input voltage overdrive. For input parameters that adhere to these constraints the propagation delay can be described as:

TNOM $\pm$ TDE (or TDT)
signal swing on the complementary input is from zero to 100 mV , the positive going overdrive would be 20 mV and the negative going overdrive would be 80 mV . The result of differing overdrive levels is that the devices have shorter propagation delays with greater overdrive because the threshold level is crossed sooner than the case of lower overdrive levels. Typically, semiconductor manufactures refer to the threshold voltage as the input offset voltage (VOS) since the threshold voltage is the sum of the externally supplied reference voltage and inherent device offset voltage.

where $\mathrm{T}_{\mathrm{NOM}}$ is the nominal propagation delay. $\mathrm{T}_{\mathrm{NOM}}$ accounts for nonuniformity introduced by temperature and voltage variability, whereas the delay dispersion parameter takes into consideration input slew rate and input voltage overdrive variability. Thus a modified propagation delay can be approximated to account for the effects of input conditions that differ from those under which the parts where tested. For example, an application may specify an ECL input with a slew rate of $0.25 \mathrm{~V} / \mathrm{NS}$, an overdrive of 17 mV and a temperature of $25^{\circ} \mathrm{C}$, the delay dispersion parameter would be 100 ps . The modified propagation delay would be

775 ps $\pm 100$ ps

# ECLinPS Lite ${ }^{\text {TM }}$ Single Gate ECL Devices 

## Features

- 275ps Package Gate Delays
- $2.0 \mathrm{GHz}+$ Flip-Flop Toggle Frequencies
- Space Efficient SOIC Packages
- Choice of ECL Compatibility: MECL $10 \mathrm{H}^{\mathrm{TM}}$ (10EL); or ECL 100K (100EL)
- Flow-Through Pinouts
- Specified Over Industrial Temperature Range: $-40^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$
- Extended VEE Range for Both 10EL and 100EL Devices

ECLinPS Lite is a family of single, essential logic primitives - gates, muxes, flops etc. - along with translators, low voltage ECL logic devices and PLL support products, housed in a space efficient, cost effective standard SOIC packages. Packaged gates switch in 250ps typ., with flops toggling at over 2 GHz .

ECLinPS Lite offers better AC specs and tighter skews than even the ECLinPSTM family. At the same time the family provides superior isolation over multiple gate logic. Its small package size makes it ideal for pin cards and other applications that require density, but not at the expense of signal integrity.

The ECLinPS Lite family utilizes the same MOSAIC IIITM process as the ECLinPS family to provide state-of-the-art bipolar process speeds. The small outline SOIC package and special design techniques serve to enhance the level of performance even further. The SOIC package shaves over $50 \%$ from the propagation delay associated with the ECLinPS family's 28-lead PLCC package. In addition special
design techniques have been applied to decrease output transition times by nearly $50 \%$, resulting in nearly a $100 \%$ improvement in bandwidth and toggle frequencies over a standard ECLinPS device.

Like the ECLinPS family, all ECLinPS Lite devices, except the EL89, are offered in 10EL and 100EL versions for compatibility with the two existing ECL standards, ECL 10H and ECL 100 K respectively. As with the ECLinPS family the AC performance of the two versions of ECLinPS Lite devices are identical, therefore AC performance will not be a factor in choosing an ECL standard. The rules for mixing 10EL and 100EL devices in a single design are outlined in the interfacing section on page 5-29.

The VEE power supply range for both ECLinPS Lite versions have been extended beyond the levels defined in the original ECL standard specifications. The lower end of the 100EL VEE limit has been decreased to -5.5 V to allow for interfacing with three level series gated 100K arrays. In addition the upper end of the 10EL VEE limit has been increased to -4.75 V to allow for use in PECL designs which use a $5 \mathrm{~V} \pm 5 \%$ supply. Note the -4.75 V VEE for 10 EL devices does not always hold for temperatures less than $25^{\circ} \mathrm{C}$ (see individual data sheets), therefore for PECL designs whose environments can fall below $25^{\circ} \mathrm{C}$ it is recommended that the 100EL devices be used to allow the designer to choose functions from the entire family.

The transfer curves, switching waveforms and parameter definitions are identical to those of the ECLinPS family. In addition the application of ECLinPS Lite devices in a system follows the same rules as previous ECL families.

## ECLinPS Lite Family Specifications

## Absolute Maximum Ratings

Beyond which device life maybe impaired. 1

| Characteristic | Symbol | Rating | Unit |
| :--- | :---: | :---: | :---: |
| Power Supply $\left(\mathrm{V}_{\mathrm{CC}}=0 \mathrm{~V}\right)$ | $\mathrm{V}_{\mathrm{EE}}$ | -8.0 to 0 | VDC |
| Input Voltage $\left(\mathrm{V}_{\mathrm{CC}}=0 \mathrm{~V}\right)$ | $\mathrm{V}_{\mathrm{I}}$ | 0 to -6.0 | VDC |
| Output CurrentContinuous <br> Surge | $\mathrm{I}_{\mathrm{out}}$ | 50 |  |
| Operating Temperature Range | $\mathrm{T}_{\mathrm{A}}$ | mA |  |
| Operating Range $\mathbf{1 , 2}$ | $\mathrm{V}_{\mathrm{EE}}$ | -40 to +85 | ${ }^{\circ}$ |

1. Unless otherwise specified on an individual data sheet.
2. Parametric values specified at: 100EL Series:
-4.20 V to -5.50 V
10EL Series:
-4.94 V to -5.50 V

## 10EL Series DC Characteristics

$\mathrm{V}_{\mathrm{EE}}=\mathrm{V}_{\mathrm{EE}}(\min )-\mathrm{V}_{\mathrm{EE}}(\max ) ; \mathrm{V}_{\mathrm{CC}}=\mathrm{GND}^{1}$

| Symbol | Characteristic | $-40^{\circ} \mathrm{C}$ |  | $0^{\circ} \mathrm{C}$ |  | $25^{\circ} \mathrm{C}$ |  | $85^{\circ} \mathrm{C}$ |  | Unit |

1. This table replaces the three tables traditionally seen in ECL 100 K data books. The same DC parameter values at $\mathrm{V}_{\mathrm{EE}}=-4.5 \mathrm{~V}$ now apply across the full $\mathrm{V}_{E E}$ range of -4.2 V to -5.5 V . Outputs are terminated through a $50 \Omega$ resistor to -2.0 V except where otherwise specified on the individual data sheets.

## Applications Information

## Introduction

The ECLinPS Lite family of products is very similar in design and performance as the multi-gate ECLinPS family. As a result the design guide and application notes written in support of the ECLinPS family are equally applicable to the new ECLinPS Lite family. The reader is encouraged to read through the ECLinPS data book to answer any general questions they may have concerning the ECLinPS Lite family. The following paragraphs will be used to describe behavior that is unique to the ECLinPS Lite family or which has not been thoroughly documented in the existing literature.

## Maximum Frequency/Bandwidth

One of the goals of the ECLinPS Lite family was to provide means for using ECL in even higher frequency applications. Much effort was placed in the reduction of the output transition times as these were the limiting factors of the frequency capability of the original ECLinPS family. With a nearly $50 \%$ reduction in output edge rates the ECLinPS Lite family's frequency capability is nearly twice that of the ECLinPS devices. Some of the 16- and 20-lead ECLinPS Lite products do not have the faster edge rates as the extra current required would push the power dissipation beyond the capabilities of the package.

The data sheets for the flip-flop devices state maximum toggle frequencies of 2.2 GHz , although impressive these values tend to underestimate the useful bandwidth of the device. Similarly the buffer devices have a 3db bandwidth ( 600 mV output swing) of about 1.4 GHz , however the devices can be useful to frequencies well above 2 GHz . The trick to using the ECLinPS Lite devices to their fullest capabilities is to take advantage of the differential I/O functions. From the data sheets for the differential devices the minimum input swing is 150 mV , a value significantly lower than the somewhat arbitrary 600 mV output chosen as the FMAX fail criteria. Figure 1 illustrates several ECLinPS Lite devices' output eye voltage versus input frequency; note for the buffer type devices the outputs produce a 150 mV eye pattern for frequencies well over 3 GHz .

Traditionalist may argue that 150 mV input swings leave no noise margins for the design, when analyzed further this is not the case. For single-ended interconnect the worst case noise margins are $\approx 150 \mathrm{mV}$ with no common mode noise rejection capabilities. For a 150 mV differential input the same 150 mV of noise margin exists, however in this case the interface also has common mode noise rejection capability and thus may provide a safer environment than a standard single-ended interface.

The purpose of this discussion is to illustrate the potential of using ECLinPS Lite devices at frequencies well above the stated maximum limits. The criteria for establishing the maximum frequency of a device was determined with
single-ended interfaces in mind, however in the $1 \mathrm{GHz}+$ realm of designs differential interconnect is predominant. For differential interconnect systems the criteria for FMAX needs to be redefined to better describe the reliable operating frequency range of a device. Under this new set of criteria the ECLinPS Lite family can be pushed well above 2.5 GHz and thus provide a cost effective means for processing very high speed signals.

Figure 1. Eye Pattern versus Frequency

## Using ECLinPS Lite in PECL Designs

PECL is an acronym for Positive ECL and simply represents using standard ECL devices in a +5.0 V environment. All of the ECLinPS Lite devices, as with the majority of all ECL devices, will operate as specified when positive power supplies are used. The reason for the use of negative power supplies with ECL is due to the fact that the output levels and internal bias levels are $\mathrm{V}_{\mathrm{CC}}$ rail referenced. Because ground is simpler to keep quiet than a power supply, it was the natural choice for the $\mathrm{V}_{\mathrm{CC}}$ bias. Because the output levels vary $1: 1$ with $V_{C C}$, differences in power supply levels between transmitter and receiver can be problematic. These problems can be eliminated if differential interconnect is used. A thorough discussion on this subject can be found in the PECL application note (Designing With PECL AN1406/D) provided in the Design Guide and Application Notes chapter (Chapter 5) of this book.

With its small size and low power the ECLinPS Lite family of products will naturally find applications in PECL form in otherwise TTL or CMOS systems. Many of these applications
will be in the area of clock distribution. Because minimizing skew is the most important aspect of clock distribution differential interconnect should be used. This not only minimizes skew, but as previously mentioned, it also eliminates problems due to $\mathrm{V}_{\mathrm{CC}}$ variation in PECL designs. Again, refer to the Motorola application note (ECL Clock Distribution Techniques - AN1405/D) dealing with using ECL in clock distribution applications for a more detailed discussion.

Figure 2. AC Coupling Architecture

An important aspect of using ECLinPS Lite in clock distribution schemes is in the interface to the clock source. By taking advantage of the AC coupling capability of the EL16, or any other differential input device which also features a $\mathrm{V}_{\mathrm{BB}}$ output, ECLinPS Lite products can be interfaced to clock sources which generate other than ECL compatible outputs. Probably the most cost efficient and simplest oscillators to choose are sinusoidal oscillators. By using the architecture of Figure 2 a sinusoidal oscillators can be used to drive ECLinPS Lite devices. The only criteria is that the amplitude of the oscillator input not exceed the upper or lower end of the CMR range when centered on the $\mathrm{V}_{\mathrm{BB}}$ reference. A larger amplitude oscillator output can be used if a lower DC bias is used or if the output of the oscillator is voltage divided prior to being coupled into the EL16.

## Input Clamp Circuitry and CMR Range

To maintain stability during open input situations all of the differential input devices employ input clamping circuitry. Because all of the inputs of ECLinPS Lite devices have internal input pulldown resistors when left open the inputs will pull down to $\mathrm{V}_{\mathrm{EE}}$. A clamp voltage will take control of the input buffer when both inputs pull lower than the clamp voltage. This clamp voltage does place a lower bound on the CMR range of a device. In the ECLinPS Lite family the internal clamp voltage is referenced to the $\mathrm{V}_{\mathrm{EE}}$ power rail, as a result if a larger CMR range is necessary the $V_{E E}$ of a device can be lowered. Each incremental lowering of $V_{E E}$ will increase the CMR range by an equivalent amount. To minimize the CMR range of devices, some of the newer members of the ECLinPS Lite family employ a different open input bias structure. These devices will pull the true input to VEE and bias the compliment input to $\mathrm{V}_{\mathrm{CC}} / 2$. This will force the output of the input buffer to a LOW state. Refer to specific data sheets to identify if this newer structure is used.

## Package Information

The package chosen for the ECLinPS Lite family is the standard SOIC package. The 8-lead, 16-lead and 20-lead SOICs are plastic surface mount packages with gull wing, 50 mil pitch leads. Figure 3 and Figure 4 illustrate the recommended PCB solder pads for the SOIC package.

Because the SOIC is a plastic package the long term reliability of a device is going to be dependent on the operating junction temperature. As the junction temperature of the device increases an intermetallic is formed between the gold bond wire and the aluminum bonding pad. This intermetallic eventually causes a void to develop and the affected pin to become an open circuit. For a more detailed discussion on the subject refer to the Package and Thermal section of the ECLinPS data book.

Figure 3. 8-, 16-Lead SOIC Solder Pad Dimensions

Figure 4. 20-Lead Wide SOIC Solder Pad Dimensions

Figure 5. SOIC Thermal Resistance

The 8-lead, 16-lead and 20-lead SOICs exhibit a thermal resistance as pictured in Figure 5. With this information as well as the power dissipation of the device in question (calculated as shown in the thermal section of the ECLinPS Data Book) the approximate junction temperature and thus theoretical lifetime can be estimated. ECLinPS Lite devices are designed with chip power levels that permit acceptable reliability levels, in most systems, under the conventional $5001 f p m(2.5 \mathrm{~m} / \mathrm{s})$ airflow. In fact, for all systems but those that operate at the maximum allowed ambient temperatures ECLinPS Lite devices will prove reliable with little or no cooling airflow.

## 4-Input OR/NOR

The MC10EL/100EL01 is a 4-input OR/NOR gate. The device is functionally equivalent to the E101 device with higher performance capabilities. With propagation delays and output transition times significantly faster than the E101 the EL01 is ideally suited for those applications which require the ultimate in AC performance.

- 230ps Propagation Delay
- High Bandwidth Output Transitions
- $75 \mathrm{k} \Omega$ Internal Input Pulldown Resistors
- >1000V ESD Protection

## 2-Input Differential AND/NAND

The MC10EL/100EL05 is a 2-input differential AND/NAND gate. The device is functionally equivalent to the E404 device with higher performance capabilities. With propagation delays and output transition times significantly faster than the E404 the EL05 is ideally suited for those applications which require the ultimate in AC performance.

Because a negative 2 -input NAND is equivalent to a 2 -input OR function, the differential inputs and outputs of the device allows the EL05 to also be used as a 2-input differential OR/NOR gate.

The differential inputs employ clamp circuitry so that under open input conditions (pulled down to $\mathrm{V}_{\mathrm{EE}}$ ) the input to the AND gate will be HIGH. In this way, if one set of inputs is open, the gate will remain active to the other input.

- 275ps Propagation Delay
- High Bandwidth Output Transitions
- $75 \mathrm{k} \Omega$ Internal Input Pulldown Resistors
- >1000V ESD Protection

1. Minimum input swing for which AC parameters are guaranteed. The device has a DC gain of $\approx 40$.
2. The CMR range is referenced to the most positive side of the differential input signal. Normal operation is obtained if the HIGH level falls within the specified range and the peak-to-peak voltage lies between $\mathrm{V}_{\text {PPmin }}$ and 1 V . The lower end of the CMR range is dependent on $\mathrm{V}_{\text {EE }}$ and is equal to $\mathrm{V}_{\mathrm{EE}}+3.0 \mathrm{~V}$.

## 2-Input XOR/XNOR

The MC10EL/100EL07 is a 2-input XOR/XNOR gate. The device is functionally equivalent to the E107 device with higher performance capabilities. With propagation delays and output transition times significantly faster than the E107 the EL07 is ideally suited for those applications which require the ultimate in AC performance.

- 260ps Propagation Delay
- High Bandwidth Output Transitions
- $75 \mathrm{k} \Omega$ Internal Input Pulldown Resistors
- >1000V ESD Protection

## 1:2 Differential Fanout Buffer

The MC10EL/100EL11 is a differential 1:2 fanout buffer. The device is functionally similar to the E111 device but with higher performance capabilities. Having within-device skews and output transition times significantly improved over the E111, the EL11 is ideally suited for those applications which require the ultimate in AC performance.

The differential inputs of the EL11 employ clamping circuitry to maintain stability under open input conditions. If the inputs are left open (pulled to $\mathrm{V}_{\mathrm{EE}}$ ) the Q outputs will go LOW.

- 265ps Propagation Delay
- 5ps Skew Between Outputs
- High Bandwidth Output Transitions
- $75 \mathrm{k} \Omega$ Internal Input Pulldown Resistors
- >1000V ESD Protection

1. Within-device skew defined as identical transitions on similar paths through a device.
2. Duty cycle skew is the difference between a TPLH and TPHL propagation delay through a device.
3. Minimum input swing for which AC parameters guaranteed. The device has a DC gain of $\approx 40$.
4. The CMR range is referenced to the most positive side of the differential input signal. Normal operation is obtained if the HIGH level falls within the specified range and the peak-to-peak voltage lies between $V_{P P}$ min and 1 V . The lower end of the CMR range is dependent on $V_{E E}$ and is equal to $\mathrm{V}_{\mathrm{EE}}+2.5 \mathrm{~V}$.

## Low Impedance Driver

The MC10EL/100EL12 is a low impedance drive buffer. With two pairs of OR/NOR outputs the device is ideally suited for high drive applications such as memory addressing. The device is a function equivalent to the E112 device with higher performance capabilities. With propagation delays significantly faster than the E112 the EL12 is ideally suited for those applications which require the ultimate in AC performance.

- 290ps Propagation Delay
- Dual Outputs for $25 \Omega$ Drive Applications
- $75 \mathrm{k} \Omega$ Internal Input Pulldown Resistors
- >1000V ESD Protection

## 1:4 Clock Distribution Chip

The MC10EL/100EL15 is a low skew 1:4 clock distribution chip designed explicitly for low skew clock distribution applications. The device can be driven by either a differential or single-ended ECL or, if positive power supplies are used, PECL input signal. If a single-ended input is to be used the $V_{\text {BB }}$ output should be connected to the CLK input and bypassed to ground via a $0.01 \mu \mathrm{~F}$ capacitor. The $\mathrm{V}_{\mathrm{BB}}$ output is designed to act as the switching reference for the input of the EL15 under single-ended input conditions, as a result this pin can only source/sink up to 0.5 mA of current.

The EL15 features a multiplexed clock input to allow for the distribution of a lower speed scan or test clock along with the high speed system clock. When LOW (or left open and pulled LOW by the input pulldown resistor) the SEL pin will select the differential clock input.

The common enable (EN) is synchronous so that the outputs will only be enabled/disabled when they are already in the LOW state. This avoids any chance of generating a runt clock pulse when the device is enabled/disabled as can happen with an asynchronous control. The internal flip flop is clocked on the falling edge of the input clock, therefore all associated specification limits are referenced to the negative edge of the clock input.

- 50ps Output-to-Output Skew
- Synchronous Enable/Disable
- Multiplexed Clock Input
- $75 \mathrm{k} \Omega$ Internal Input Pulldown Resistors
- >1000V ESD Protection

1. 10EL circuits are designed to meet the DC specifications shown in the table after thermal equilibrium has been established. The circuit is in a test socket or mounted on a printed circuit board and transverse airflow greater than 500 lfpm is maintained. Outputs are terminated through a $50 \Omega$ resistor to -2.0 V except where otherwise specified on the individual data sheets.

1. Skews are specified for identical LOW-to-HIGH or HIGH-to-LOW transitions.
2. Minimum input swing for which AC parameters guaranteed. The device has a DC gain of $\approx 40$.
3. The CMR range is referenced to the most positive side of the differential input signal. Normal operation is obtained if the HIGH level falls within the specified range and the peak-to-peak voltage lies between $V_{P P}$ min and 1 V . The lower end of the CMR range is dependent on $V_{E E}$ and is equal to $\mathrm{V}_{\mathrm{EE}}+2.5 \mathrm{~V}$.

## Differential Receiver

The MC10EL/100EL16 is a differential receiver. The device is functionally equivalent to the E116 device with higher performance capabilities. With output transition times significantly faster than the E116 the EL16 is ideally suited for interfacing with high frequency sources.

The EL16 provides a $V_{B B}$ output for either single-ended use or as a DC bias for AC coupling to the device. The $\mathrm{V}_{\mathrm{BB}}$ pin should be used only as a bias for the EL16 as its current sink/source capability is limited. Whenever used, the $\mathrm{V}_{\mathrm{BB}}$ pin should be bypassed to ground via a $0.01 \mu \mathrm{f}$ capacitor.

Under open input conditions (pulled to $\mathrm{V}_{\mathrm{EE}}$ ) internal input clamps will force the Q output LOW.

- 250ps Propagation Delay
- High Bandwidth Output Transitions
- $75 \mathrm{k} \Omega$ Internal Input Pulldown Resistors
- >1000V ESD Protection

MC10EL16 MC100EL16

## D Flip-Flop <br> With Set and Reset

## MC10EL31 MC100EL31

The MC10EL/100EL31 is a D flip-flop with set and reset. The device is functionally equivalent to the E131 device with higher performance capabilities. With propagation delays and output transition times significantly faster than the E131 the EL31 is ideally suited for those applications which require the ultimate in AC performance.

Both set and reset inputs are asynchronous, level triggered signals. Data enters the master portion of the flip-flop when clock is LOW and is transferred to the slave, and thus the outputs, upon a positive transition of the clock.

- 475ps Propagation Delay
- 2.8 GHz Toggle Frequency
- $75 \mathrm{k} \Omega$ Internal Input Pulldown Resistors
- >1000V ESD Protection

## $\div 2$ Divider

The MC10EL/100EL32 is an integrated $\div 2$ divider. The differential clock inputs and the $\mathrm{V}_{\mathrm{BB}}$ allow a differential, single-ended or AC coupled interface to the device. If used, the $\mathrm{V}_{\mathrm{BB}}$ output should be bypassed to ground with a $0.01 \mu \mathrm{~F}$ capacitor. Also note that the $\mathrm{V}_{\mathrm{BB}}$ is designed to be used as an input bias on the EL32 only, the $\mathrm{V}_{\mathrm{BB}}$ output has limited current sink and source capability.

The reset pin is asynchronous and is asserted on the rising edge. Upon power-up, the internal flip-flop will attain a random state; the reset allows for the synchronization of multiple EL32's in a system.

- 510ps Propagation Delay
- 3.0GHz Toggle Frequency
- High Bandwidth Output Transitions
- $75 \mathrm{k} \Omega$ Internal Input Pulldown Resistors
- >1000V ESD Protection

## $\div 4$ Divider

The MC10EL/100EL33 is an integrated $\div 4$ divider. The differential clock inputs and the $\mathrm{V}_{\mathrm{BB}}$ allow a differential, single-ended or AC coupled interface to the device. If used, the $\mathrm{V}_{\mathrm{BB}}$ output should be bypassed to ground with a $0.01 \mu \mathrm{~F}$ capacitor. Also note that the $\mathrm{V}_{\mathrm{BB}}$ is designed to be used as an input bias on the EL33 only, the $\mathrm{V}_{\mathrm{BB}}$ output has limited current sink and source capability.

The reset pin is asynchronous and is asserted on the rising edge. Upon power-up, the internal flip-flops will attain a random state; the reset allows for the synchronization of multiple EL33's in a system.

- 650ps Propagation Delay
- 4.0 GHz Toggle Frequency
- High Bandwidth Output Transitions
- $75 \mathrm{k} \Omega$ Internal Input Pulldown Resistors
- >1000V ESD Protection

## $\div 2, \div 4, \div 8$ Clock Generation Chip

The MC10/100EL34 is a low skew $\div 2, \div 4, \div 8$ clock generation chip designed explicitly for low skew clock generation applications. The internal dividers are synchronous to each other, therefore, the common output edges are all precisely aligned. The device can be driven by either a differential or single-ended ECL or, if positive power supplies are used, PECL input signal. In addition, by using the $\mathrm{V}_{\mathrm{BB}}$ output, a sinusoidal source can be AC coupled into the device (see Interfacing section of the ECLinPS ${ }^{\text {M }}$ Data Book DL140/D). If a single-ended input is to be used, the $V_{B B}$ output should be connected to the CLK input and bypassed to ground via a $0.01 \mu \mathrm{~F}$ capacitor. The $\mathrm{V}_{\mathrm{BB}}$ output is designed to act as the switching reference for the input of the EL34 under single-ended input conditions, as a result, this pin can only source/sink up to 0.5 mA of current.

The common enable ( $\overline{\mathrm{EN}}$ ) is synchronous so that the internal dividers will only be enabled/disabled when the internal clock is already in the LOW state. This avoids any chance of generating a runt clock pulse on the internal clock when the device is enabled/disabled as can happen with an asynchronous control. An internal runt pulse could lead to losing synchronization between the internal divider stages. The internal enable flip-flop is clocked on the falling edge of the input clock, therefore, all associated specification limits are referenced to the negative edge of the clock input.

Upon startup, the internal flip-flops will attain a random state; the master reset (MR) input allows for the synchronization of the internal dividers, as well as multiple EL34s in a system.

- 50ps Output-to-Output Skew
- Synchronous Enable/Disable
- Master Reset for Synchronization

The EN signal will freeze the internal clocks to the flip-flops on the first falling edge of CLK after its assertion. The internal dividers will maintain their state during the internal clock freeze and will return to clocking once the internal clocks are unfrozen. The outputs will transition to their next states in the same manner, time and relationship as they would have had the EN signal not been asserted.

## Differential Clock D Flip-Flop

The MC10EL/100EL51 is a differential clock D flip-flop with reset. The device is functionally similar to the E151 device with higher performance capabilities. With propagation delays and output transition times significantly faster than the E151 the EL51 is ideally suited for those applications which require the ultimate in AC performance.

The reset input is an asynchronous, level triggered signal. Data enters the master portion of the flip-flop when the clock is LOW and is transferred to the slave, and thus the outputs, upon a positive transition of the clock. The differential clock inputs of the EL51 allow the device to be used as a negative edge triggered flip-flop.

The differential input employs clamp circuitry to maintain stability under open input (pulled down to $\mathrm{V}_{\mathrm{EE}}$ ) conditions.

1. Minimum input swing for which AC parameters are guaranteed.
2. The CMR range is referenced to the most positive side of the differential input signal. Normal operation is obtained if the HIGH level falls within the specified range and the peak-to-peak voltage lies between $\mathrm{V}_{\text {PPmin }}$ and 1 V . The lower end of the CMR range is dependent on $\mathrm{V}_{\text {EE }}$ and is equal to $\mathrm{V}_{\mathrm{EE}}+2.5 \mathrm{~V}$.

## Differential Data and Clock D Flip-FIop

The MC10EL/100EL52 is a differential data, differential clock D flip-flop with reset. The device is functionally equivalent to the E452 device with higher performance capabilities. With propagation delays and output transition times significantly faster than the E452 the EL52 is ideally suited for those applications which require the ultimate in AC performance.

Data enters the master portion of the flip-flop when the clock is LOW and is transferred to the slave, and thus the outputs, upon a positive transition of the clock. The differential clock inputs of the EL52 allow the device to also be used as a negative edge triggered device.

The EL52 employs input clamping circuitry so that under open input conditions (pulled down to $\mathrm{V}_{\mathrm{EE}}$ ) the outputs of the device will remain stable.

- 365ps Propagation Delay
- 2.0 GHz Toggle Frequency
- $75 \mathrm{k} \Omega$ Internal Input Pulldown Resistors
- >1000V ESD Protection

## 4:1 Differential Multiplexer

The MC10/100EL57 is a fully differential 4:1 multiplexer. By leaving the SEL1 line open (pulled LOW via the input pulldown resistors) the device can also be used as a differential 2:1 multiplexer with SELO input selecting between D0 and D1. The fully differential architecture of the EL57 makes it ideal for use in low skew applications such as clock distribution.

The SEL1 is the most significant select line. The binary number applied to the select inputs will select the same numbered data input (i.e., 00 selects DO).

Multiple $V_{B B}$ outputs are provided for single-ended or AC coupled interfaces. In these scenarios, the $\mathrm{V}_{\mathrm{BB}}$ output should be connected to the data bar inputs and bypassed via a $0.01 \mu \mathrm{~F}$ capacitor to ground. Note that the $V_{\mathrm{BB}}$ output can source/sink up to 0.5 mA of current without upsetting the voltage level.

- Useful as Either 4:1 or 2:1 Multiplexer
- VBB Output for Single-Ended Operation
- $75 \mathrm{k} \Omega$ Internal Input Pulldown Resistors
- $>1000 \mathrm{~V}$ ESD Protection

## Coaxial Cable Driver

The MC10EL/100EL89 is a differential fanout gate specifically designed to drive coaxial cables. The device is especially useful in Digital Video Broadcasting applications; for this application, since the system is polarity free, each output can be used as an idependent driver. The driver boasts a gain of approximately 40 and produces output swings twice as large as a standard ECL output. When driving a coaxial cable, proper termination is required at both ends of the line to minimize signal loss. The 1.6 V output swings allow for termination at both ends of the cable, while maintaining the required 800 mV swing at the receiving end of the cable. Because of the larger output swings, the device cannot be terminated into the standard -2.0 V . All of the DC parameters are tested with a $50 \Omega$ to -3.0 V load. The driver accepts a standard differential ECL input and can run off of the Digital Video Broadcast standard -5.0 V supply.

- 375ps Propagation Delay
- 1.6V Output Swings
- $75 \mathrm{k} \Omega$ Internal Input Pulldown Resistors
- >1000V ESD Protection

1. Minimum input swing for which AC parameters are guaranteed. The device has a DC gain of $\approx 40$.
2. The CMR range is referenced to the most positive side of the differential input signal. Normal operation is obtained if the HIGH level falls within the specified range and the peak-to-peak voltage lies between $\mathrm{V}_{\text {PP }}$ min and 1 V . The lower end of the CMR range is dependent on $\mathrm{V}_{\text {EE }}$ and is equal to $\mathrm{V}_{\mathrm{EE}}+2.5 \mathrm{~V}$.

## ECLinPS Lite Translators

3

## TTL to Differential PECL Translator

The MC10ELT/100ELT20 is a TTL to differential PECL translator. Because PECL (Positive ECL) levels are used only +5 V and ground are required. The small outline 8 -lead SOIC package and the single gate of the ELT20 makes it ideal for those applications where space, performance and low power are at a premium. Because the mature MOSAIC 1.5 process is used, low cost can be added to the list of features.

The ELT20 is available in both ECL standards: the 10ELT is compatible with positive MECL 10H logic levels while the 100ELT is compatible with positive ECL 100K logic levels.

- 1.5ns Typical Propagation Delay
- Differential PECL Outputs
- Small Outline SOIC Package
- PNP TTL Inputs for Minimal Loading
- Flow Through Pinouts

## Differential PECL to TTL Translator

## MC10ELT21 MC100ELT21

The MC10ELT/100ELT21 is a differential PECL to TTL translator. Because PECL (Positive ECL) levels are used only +5 V and ground are required. The small outline 8 -lead SOIC package and the single gate of the ELT21 makes it ideal for those applications where space, performance and low power are at a premium. Because the mature MOSAIC 1.5 process is used, low cost can be added to the list of features.

The VBB output allows the ELT21 to also be used in a single-ended input mode. In this mode the $\mathrm{V}_{\mathrm{BB}}$ output is tied to the IN input for a non-inverting buffer or the IN input for an inverting buffer. If used the $\mathrm{V}_{\mathrm{BB}}$ pin should be bypassed to ground via a $0.01 \mu \mathrm{~F}$ capacitor.

The ELT21 is available in both ECL standards: the 10ELT is compatible with positive MECL 10H logic levels while the 100ELT is compatible with positive ECL 100K logic levels.

- 3.5ns Typical Propagation Delay
- Differential PECL Inputs
- Small Outline SOIC Package
- 24 mA TTL Output
- Flow Through Pinouts

## Dual Differential PECL to TTL Translator

The MC100ELT23 is a dual differential PECL to TTL translator. Because PECL (Positive ECL) levels are used only +5 V and ground are required. The small outline 8 -lead SOIC package and the dual gate design of the ELT23 makes it ideal for applications which require the translation of a clock and a data signal. Because the mature MOSAIC 1.5 process is used, low cost can be added to the list of features.

The ELT23 is available in only the ECL 100K standard. Since there are no PECL outputs or an external $\mathrm{V}_{\mathrm{BB}}$ reference, the ELT23 does not require both ECL standard versions. The PECL inputs are differential; there is no specified difference between the differential input 10 H and 100 K standards. Therefore, the MC100ELT23 can accept any standard differential PECL input referenced from a $\mathrm{V}_{\mathrm{CC}}$ of 5.0 V .

## Differential ECL to TTL Translator

The MC10ELT/100ELT25 is a differential ECL to TTL translator. Because ECL levels are used $\mathrm{a}+5 \mathrm{~V}$, -5.2 V (or -4.5 V ) and ground are required. The small outline 8 -lead SOIC package and the single gate of the ELT25 makes it ideal for those applications where space, performance and low power are at a premium. Because the mature MOSAIC 1.5 process is used, low cost can be added to the list of features.

The $\mathrm{V}_{\mathrm{BB}}$ output allows the ELT25 to also be used in a single-ended input mode. In this mode the $V_{B B}$ output is tied to the IN input for a non-inverting buffer or the IN input for an inverting buffer. If used the $\mathrm{V}_{\mathrm{BB}}$ pin should be bypassed to ground via a $0.01 \mu \mathrm{~F}$ capacitor.

The ELT25 is available in both ECL standards: the 10ELT is compatible with MECL 10 H logic levels while the 100ELT is compatible with ECL 100K logic levels.

- 2.6ns Typical Propagation Delay
- Differential ECL Inputs
- Small Outline SOIC Package
- 24 mA TTL Outputs
- Flow Through Pinouts

## Product Preview <br> 1:2 Fanout Differential PECL to TTL Translator

The MC10ELT/100ELT26 is a 1:2 fanout differential PECL to TTL translator. Because PECL (Positive ECL) levels are used only +5 V and ground are required. The small outline 8-lead SOIC package and the 1:2 fanout design of the ELT23 makes it ideal for applications which require the low skew duplication of a signal in a tightly packed PC board. Because the mature MOSAIC 1.5 process is used, low cost can be added to the list of features.

The $\mathrm{V}_{\mathrm{BB}}$ output allows the ELT26 to also be used in a single-ended input mode. In this mode the $\mathrm{V}_{\mathrm{BB}}$ output is tied to the IN input for a non-inverting buffer or the IN input for an inverting buffer. If used the $\mathrm{V}_{\mathrm{BB}}$ pin should be bypassed to ground via a $0.01 \mu \mathrm{~F}$ capacitor.

The ELT26 is available in both ECL standards: the 10ELT is compatible with positive MECL 10H logic levels while the 100ELT is compatible with positive ECL 100K logic levels.

- 3.5ns Typical Propagation Delay
- $<500$ ps Typical Output to Output Skew
- Differential PECL Inputs
- Small Outline SOIC Package
- 24 mA TTL Outputs
- Flow Through Pinouts

## Advance Information TTL to Differential PECL/Differential PECL to TTL Translator

The MC10ELT/100ELT28 is a differential PECL to TTL translator and a TTL to differential PECL translator in a single package. Because PECL (Positive ECL) levels are used only +5 V and ground are required. The small outline 8-lead SOIC package and the dual translation design of the ELT28 makes it ideal for applications which are sending and receiving signals across a backplane. Because the mature MOSAIC 1.5 process is used, low cost can be added to the list of features.

The ELT28 is available in both ECL standards: the 10ELT is compatible with positive MECL 10H logic levels while the 100ELT is compatible with positive ECL 100K logic levels.

## Low-Voltage 1:9 Differential ECL/PECL Clock Driver

The MC100LVE111 is a low skew 1-to-9 differential driver, designed with clock distribution in mind. The MC100LVE111's function and performance are similar to the popular MC100E111, with the added feature of low voltage operation. It accepts one signal input, which can be either differential or single-ended if the $\mathrm{V}_{\mathrm{BB}}$ output is used. The signal is fanned out to 9 identical differential outputs.

- 200ps Part-to-Part Skew
- 50ps Output-to-Output Skew
- Differential Design
- VBB Output
- Voltage and Temperature Compensated Outputs
- Low Voltage VEE Range of -3.0 to -3.8 V
- $75 \mathrm{k} \Omega$ Input Pulldown Resistors

The LVE111 is specifically designed, modeled and produced with low skew as the key goal. Optimal design and layout serve to minimize gate to gate skew within a device, and empirical modeling is used to determineprocess control limits that ensure consistent tpd distributions from lot to lot. The net result is a dependable, guaranteed low skew device.

To ensure that the tight skew specification is met it is necessary that both sides of the differential output are terminated into $50 \Omega$, even if only one side is being used. In most applications, all nine differential pairs will be used and therefore terminated. In the case where fewer than nine pairs are used, it is necessary to terminate at least the output pairs on the same package side as the pair(s) being used on that side, in order to maintain minimum skew. Failure to do this will result in small degradations of propagation delay (on the order of 10-20ps) of the output(s) being used which, while not being catastrophic to most designs, will mean a loss of skew margin.

The MC100LVE111, as with most other ECL devices, can be operated from a positive $\mathrm{V}_{\mathrm{CC}}$ supply in PECL mode. This allows the LVE111 to be used for high performance clock distribution in +3.3 V systems. Designers can take advantage of the LVE111's performance to distribute low skew clocks across the backplane or the board. In a PECL environment, series or Thevenin line terminations are typically used as they require no additional power supplies. For systems incorporating GTL, parallel termination offers the lowest power by taking advantage of the 1.2 V supply as a terminating voltage. For more information on using PECL, designers should refer to Motorola Application Note AN1406/D.

1. The differential propagation delay is defined as the delay from the crossing points of the differential input signals to the crossing point of the differential output signals. See Definitions and Testing of ECLinPS AC Parameters in Chapter 1 (page 1-12).
2. The single-ended propagation delay is defined as the delay from the $50 \%$ point of the input signal to the $50 \%$ point of the output signal. See Definitions and Testing of ECLinPS AC Parameters in Chapter 1 (page 1-12).
3. The within-device skew is defined as the worst case difference between any two similar delay paths within a single device
4. $V_{P P}(\min )$ is defined as the minimum input differential voltage which will cause no increase in the propagation delay. The $V_{P P}(\mathrm{~min})$ is $A C$ limited for the E111 as a differential input as low as 50 mV will still produce full ECL levels at the output.
5. $\mathrm{V}_{\mathrm{CMR}}$ is defined as the range within which the $\mathrm{V}_{\mathrm{IH}}$ level may vary, with the device still meeting the propagation delay specification. The $\mathrm{V}_{\mathrm{IL}}$ level must be such that the peak to peak voltage is less than 1.0 V and greater than or equal to $\mathrm{V}_{\mathrm{PP}}(\mathrm{min})$.

## Low Voltage 16:1 Multiplexer

The MC100LVE164 is a $16: 1$ multiplexer with a differential output. The select inputs (SELO, 1, 2, 3 ) control which one of the sixteen data inputs (A0-A15) is propagated to the output. The device is functionally equivalent to the MC100E164 except it operates from a -3.3 V supply. The device is packaged in the 32-lead TQFP. The TQFP has a $7 \times 7 \mathrm{~mm}$ body with a 0.8 mm lead pitch.

Special attention to the design layout results in a typical skew between the 16 inputs of only 50 ps.

- 850ps Data Input to Output
- Differential Output
- Extended 100E VEE Range of -3.0 V to -3.8 V
- Internal $75 \mathrm{k} \Omega$ Input Pulldown Resistors

## Low Voltage Dual 1:4, 1:5 Differential Fanout Buffer ECL/PECL Compatible

The MC100LVE210 is a low voltage, low skew dual differential ECL fanout buffer designed with clock distribution in mind. The device features two fanout buffers, a 1:4 and a 1:5 buffer, on a single chip. The device features fully differential clock paths to minimize both device and system skew. The dual buffer allows for the fanout of two signals through a single chip, thus reducing the skew between the two fundamental signals from a part-to-part skew down to an output-to-output skew. This capability reduces the skew by a factor of 4 as compared to using two LVE111's to accomplish the same task. The MC100LVE210 works from a -3.3 V supply while the MC100E210 provides identical function and performance from a standard -4.5 V 100E voltage supply.

- Dual Differential Fanout Buffers
- 200ps Part-to-Part Skew
- 50ps Typical Output-to-Output Skew
- Low Voltage ECL/PECL Compatible
- 28-lead PLCC Packaging

For applications which require a single-ended input, the $V_{\mathrm{BB}}$ reference voltage is supplied. For single-ended input applications the $V_{B B}$ reference should be connected to the CLK input and bypassed to ground via a $0.01 \mu \mathrm{f}$ capacitor. The input signal is then driven into the CLK input.

To ensure that the tight skew specification is met it is necessary that both sides of the differential output are terminated into $50 \Omega$, even if only one side is being used. In most applications all nine differential pairs will be used and therefore terminated. In the case where fewer than nine pairs are used it is necessary to terminate at least the output pairs adjacent to the output pair being used in order to maintain minimum skew. Failure to follow this guideline will result in small degradations of propagation delay (on the order of 10-20ps) of the outputs being used, while not catastrophic to most designs this will result in an increase in skew. Note that the package corners isolate outputs from one another such that the guideline expressed above holds only for outputs on the same side of the package.

The MC100LVE210, as with most ECL devices, can be operated from a positive $V_{C C}$ supply in PECL mode. This allows the LVE210 to be used for high performance clock distribution in +3.3V systems. Designers can take advantage of the LVE210's performance to distribute low skew clocks across the backplane or the board. In a PECL environment series or Thevenin line terminations are typically used as they require no additional power supplies, if parallel termination is desired a terminating voltage of $\mathrm{V}_{\mathrm{CC}}-2.0 \mathrm{~V}$ will need to be provided. For more information on using PECL, designers should refer to Motorola Application Note AN1406/D.

1. The differential propagation delay is defined as the delay from the crossing points of the differential input signals to the crossing point of the differential output signals. See Definitions and Testing of ECLinPS AC Parameters in Chapter 1 (page 1-12).
2. The single-ended propagation delay is defined as the delay from the $50 \%$ point of the input signal to the $50 \%$ point of the output signal. See Definitions and Testing of ECLinPS AC Parameters in Chapter 1 (page 1-12).
3. The within-device skew is defined as the worst case difference between any two similar delay paths within a single device.
4. $V_{P P}(\min )$ is defined as the minimum input differential voltage which will cause no increase in the propagation delay. The $V_{P P}(\mathrm{~min})$ is $A C$ limited for the E210 as a differential input as low as 50 mV will still produce full ECL levels at the output.
5. $\mathrm{V}_{\mathrm{CMR}}$ is defined as the range within which the $\mathrm{V}_{\mathrm{IH}}$ level may vary, with the device still meeting the propagation delay specification. The $\mathrm{V}_{\mathrm{IL}}$ level must be such that the peak to peak voltage is less than 1.0 V and greater than or equal to $\mathrm{VPP}_{\mathrm{PP}}(\mathrm{min})$.

## Low Voltage 1:15 Differential ECL/PECL Clock Driver

The MC100LVE222 is a low voltage, low skew 1:15 differential ECL fanout buffer designed with clock distribution in mind. The device features fully differential clock paths to minimize both device and system skew. The LVE222 can be used as a simple fanout buffer or outputs can be configured to provide half frequency outputs. The combination of $1 x$ and $1 / 2 x$ frequencies is flexible providing for a myriad of combinations. All timing differences between the $1 x$ and $1 / 2 x$ signals are compensated for internal to the chip so that the output-to-output skew is identical regardless of what output frequencies are selected.

- Fifteen Differential Outputs
- 200ps Part-to-Part Skew
- 50ps Output-to-Output Skew
- Selectable $1 \times$ or $1 / 2 x$ Frequency Outputs
- Low Voltage ECL/PECL Compatible
- TQFP Packaging

For applications which require a single-ended input, the $V_{B B}$ reference voltage is supplied. For single-ended input applications the $V_{B B}$ reference should be connected to the CLK input and bypassed to ground via a $0.01 \mu \mathrm{f}$ capacitor. The input signal is then driven into the CLK input.

To ensure that the tight skew specification is met it is necessary that both sides of the differential output are terminated into $50 \Omega$, even if only one side is being used. In most applications all fifteen differential pairs will be used and therefore terminated. In the case where fewer than fifteen pairs are used it is necessary to terminate at least the output pairs adjacent to the output pair being used in order to maintain minimum skew. Failure to follow this guideline will result in small degradations of propagation delay (on the order of 10-20ps) of the outputs being used, while not catastrophic to most designs this will result in an increase in skew. Note that the package corners isolate outputs from one another such that the guideline expressed above holds only for outputs on the same side of the package.

The MC100LVE222, as with most ECL devices, can be operated from a positive $V_{C C}$ supply in PECL mode. This allows the LVE222 to be used for high performance clock distribution in +3.3 V systems. Designers can take advantage of the LVE222's performance to distribute low skew clocks across the backplane or the board. In a PECL environment series or Thevenin line terminations are typically used as they require no additional power supplies, if parallel termination is desired a terminating voltage of $\mathrm{V}_{\mathrm{CC}}-2.0 \mathrm{~V}$ will need to be provided. For more information on using PECL, designers should refer to Motorola Application Note AN1406/D.

The MC100LVE222 is packaged in the 52-lead TQFP package. For a 3.3 V supply this package provides the optimum performance and minimizes board space requirements. The LVE222 will operate from a standard 100E 4.5 V supply, however for this supply voltage special thermal considerations are required. The 52-lead TQFP utilizes a $10 \times 10 \mathrm{~mm}$ body with a lead pitch of 0.65 mm .

1. The differential propagation delay is defined as the delay from the crossing points of the differential input signals to the crossing point of the differential output signals. See Definitions and Testing of ECLinPS AC Parameters in Chapter 1 (page 1-12).
2. The single-ended propagation delay is defined as the delay from the $50 \%$ point of the input signal to the $50 \%$ point of the output signal. See Definitions and Testing of ECLinPS AC Parameters in Chapter 1 (page 1-12).
3. The within-device skew is defined as the worst case difference between any two similar delay paths within a single device.
4. $V_{P P}(\min )$ is defined as the minimum input differential voltage which will cause no increase in the propagation delay. The $V_{P P}(\mathrm{~min})$ is $A C$ limited for the LVE222 as a differential input as low as 50 mV will still produce full ECL levels at the output.
5. $\mathrm{V}_{\mathrm{CMR}}$ is defined as the range within which the $\mathrm{V}_{I H}$ level may vary, with the device still meeting the propagation delay specification. The $\mathrm{V}_{I L}$ level must be such that the peak to peak voltage is less than 1.0 V and greater than or equal to $\mathrm{V}_{\mathrm{PP}}(\mathrm{min})$.

## Low Voltage 2:8 Differential Fanout Buffer ECL/PECL Compatible

The MC100LVE310 is a low voltage, low skew $2: 8$ differential ECL fanout buffer designed with clock distribution in mind. The device features fully differential clock paths to minimize both device and system skew. The LVE310 offers two selectable clock inputs to allow for redundant or test clocks to be incorporated into the system clock trees. The MC100E310 is pin compatible to the National 100310 device. The MC100LVE310 works from a -3.3 V supply while the MC100E310 provides identical function and performance from a standard -4.5V 100E voltage supply.

- Dual Differential Fanout Buffers
- 200ps Part-to-Part Skew
- 50ps Output-to-Output Skew
- Low Voltage ECL/PECL Compatible
- 28-lead PLCC Packaging

For applications which require a single-ended input, the $V_{B B}$ reference voltage is supplied. For single-ended input applications the $V_{B B}$ reference should be connected to the CLK input and bypassed to ground via a $0.01 \mu \mathrm{f}$ capacitor. The input signal is then driven into the CLK input.

To ensure that the tight skew specification is met it is necessary that both sides of the differential output are terminated into $50 \Omega$, even if only one side is being used. In most applications all nine differential pairs will be used and therefore terminated. In the case where fewer than nine pairs are used it is necessary to terminate at least the output pairs adjacent to the output pair being used in order to maintain minimum skew. Failure to follow this guideline will result in small degradations of propagation delay (on the order of $10-20 \mathrm{ps}$ ) of the outputs being used, while not catastrophic to most designs this will result in an increase in skew. Note that the package corners isolate outputs from one another such that the guideline expressed above holds only for outputs on the same side of the package.

The MC100LVE310, as with most ECL devices, can be operated from a positive $V_{C C}$ supply in PECL mode. This allows the LVE310 to be used for high performance clock distribution in +3.3 V systems. Designers can take advantage of the LVE310's performance to distribute low skew clocks across the backplane or the board. In a PECL environment series or Thevenin line terminations are typically used as they require no additional power supplies, if parallel termination is desired a terminating voltage of $\mathrm{V}_{\mathrm{CC}}-2.0 \mathrm{~V}$ will need to be provided. For more information on using PECL, designers should refer to Motorola Application Note AN1406/D.

1. The differential propagation delay is defined as the delay from the crossing points of the differential input signals to the crossing point of the differential output signals. See Definitions and Testing of ECLinPS AC Parameters in Chapter 1 (page 1-12).
2. The single-ended propagation delay is defined as the delay from the $50 \%$ point of the input signal to the $50 \%$ point of the output signal. See Definitions and Testing of ECLinPS AC Parameters in Chapter 1 (page 1-12).
3. The within-device skew is defined as the worst case difference between any two similar delay paths within a single device.
4. $V_{P P}(\min )$ is defined as the minimum input differential voltage which will cause no increase in the propagation delay. The $V_{P P}(\mathrm{~min})$ is $A C$ limited for the LVE310 as a differential input as low as 50 mV will still produce full ECL levels at the output.
5. $\mathrm{V}_{\mathrm{CMR}}$ is defined as the range within which the $\mathrm{V}_{\mathrm{IH}}$ level may vary, with the device still meeting the propagation delay specification. The $\mathrm{V}_{\mathrm{IL}}$ level must be such that the peak to peak voltage is less than 1.0 V and greater than or equal to $\mathrm{V}_{\mathrm{PP}}(\mathrm{min})$.

1. The differential propagation delay is defined as the delay from the crossing points of the differential input signals to the crossing point of the differential output signals. See Definitions and Testing of ECLinPS AC Parameters in Chapter 1 (page 1-12).
2. The single-ended propagation delay is defined as the delay from the $50 \%$ point of the input signal to the $50 \%$ point of the output signal. See Definitions and Testing of ECLinPS AC Parameters in Chapter 1 (page 1-12).
3. The within-device skew is defined as the worst case difference between any two similar delay paths within a single device.
4. $V_{P P}(\mathrm{~min})$ is defined as the minimum input differential voltage which will cause no increase in the propagation delay. The $V_{P P}(\mathrm{~min})$ is $A C$ limited for the E310 as a differential input as low as 50 mV will still produce full ECL levels at the output.
5. $\mathrm{V}_{\mathrm{CMR}}$ is defined as the range within which the $\mathrm{V}_{\mathrm{IH}}$ level may vary, with the device still meeting the propagation delay specification. The $\mathrm{V}_{\mathrm{IL}}$ level must be such that the peak to peak voltage is less than 1.0 V and greater than or equal to $\mathrm{V}_{\mathrm{PP}}(\mathrm{min})$.

## Low Voltage <br> 1:2 Differential Fanout Buffer

The MC100LVEL11 is a differential 1:2 fanout buffer. The device is functionally similar to the E111 device but with higher performance capabilities. Having within-device skews and output transition times significantly improved over the E111, the LVEL11 is ideally suited for those applications which require the ultimate in AC performance.

The differential inputs of the LVEL11 employ clamping circuitry to maintain stability under open input conditions. If the inputs are left open (pulled to $\mathrm{V}_{\mathrm{EE}}$ ) the Q outputs will go LOW.

- 330ps Propagation Delay
- 5ps Skew Between Outputs
- High Bandwidth Output Transitions
- $75 \mathrm{k} \Omega$ Internal Input Pulldown Resistors
- >2000V ESD Protection

1. Within-device skew defined as identical transitions on similar paths through a device.
2. Duty cycle skew is the difference between a TPLH and TPHL propagation delay through a device.
3. Minimum input swing for which AC parameters guaranteed. The device will function properly with input swings below 200mV, however, AC delays may move outside of the specified range. The device has a DC gain of $\approx 40$.
4. The CMR range is referenced to the most positive side of the differential input signal. Normal operation is obtained if the HIGH level falls within the specified range and the peak-to-peak voltage lies between $V_{P P}$ min and 1 V . The lower end of the CMR range varies $1: 1$ with $V_{E E}$. The number in the spec table assumes a nominal $\mathrm{V}_{\mathrm{EE}}=-3.3 \mathrm{~V}$. Note for PECL operation, the $\mathrm{V}_{\mathrm{CMR}}(\mathrm{min})$ will be fixed at $3.3 \mathrm{~V}-\left|\mathrm{V}_{\mathrm{CMR}}(\mathrm{min})\right|$.

Figure 1. Output Swing versus Frequency

## Dual 1:3 Fanout Buffer

The MC100LVEL13 is a dual, fully differential 1:3 fanout buffer. The MC100EL13 is pin and functionally equivalent to the MC100LVEL13 but is specified for operation at the standard 100E ECL voltage supply. The Low Output-Output Skew of the device makes it ideal for distributing two different frequency synchronous signals.

The differential inputs have special circuitry which ensures device stability under open input conditions. When both differential inputs are left open the D input will pull down to $\mathrm{V}_{\mathrm{EE}}$, The D input will bias around $\mathrm{V}_{\mathrm{CC}} / 2$ and the Q output will go LOW.

- Differential Inputs and Outputs
- 20-Lead SOIC Packaging
- 500ps Typical Propagation Delays
- 50ps Output-Output Skews
- Supports Both Standard and Low Voltage 100K ECL
- >2000V ESD Protection

1. Minimum input swing for which AC parameters guaranteed. The device has a DC gain of $\approx 40$.
2. The CMR range is referenced to the most positive side of the differential input signal. Normal operation is obtained if the HIGH level falls within the specified range and the peak-to-peak voltage lies between $\mathrm{V}_{P P}$ min and 1 V . The lower end of the CMR range varies $1: 1$ with $\mathrm{V}_{\mathrm{EE}}$. The numbers in the spec table assume a nominal $\mathrm{V}_{\mathrm{EE}}=-4.5 \mathrm{~V}$. Note for PECL operation, the $\mathrm{V}_{\mathrm{CMR}}(\mathrm{min})$ will be fixed at $5.0 \mathrm{~V}-\left|\mathrm{V}_{\mathrm{CMR}}(\mathrm{min})\right|$.

## 1:5 Clock Distribution Chip

The MC100LVEL/100EL14 is a low skew 1:5 clock distribution chip designed explicitly for low skew clock distribution applications. The device can be driven by either a differential or single-ended ECL or, if positive power supplies are used, PECL input signal. The LVEL14 is functionally and pin compatible with the EL14 but is designed to operate in ECL or PECL mode for a voltage supply range of -3.0 V to -3.8 V ( or 3.0 V to 3.8 V ). If a single-ended input is to be used the $\mathrm{V}_{\mathrm{BB}}$ output should be connected to the CLK input and bypassed to ground via a $0.01 \mu \mathrm{~F}$ capacitor. The $\mathrm{V}_{\text {BB }}$ output is designed to act as the switching reference for the input of the LVEL14 under single-ended input conditions, as a result this pin can only source/sink up to 0.5 mA of current.

The LVEL14 features a multiplexed clock input to allow for the distribution of a lower speed scan or test clock along with the high speed system clock. When LOW (or left open and pulled LOW by the input pulldown resistor) the SEL pin will select the differential clock input.

The common enable (EN) is synchronous so that the outputs will only be enabled/disabled when they are already in the LOW state. This avoids any chance of generating a runt clock pulse when the device is enabled/disabled as can happen with an asynchronous control. The internal flip flop is clocked on the falling edge of the input clock, therefore all associated specification limits are referenced to the negative edge of the clock input.

- 50ps Output-to-Output Skew
- Synchronous Enable/Disable
- Multiplexed Clock Input
- $75 \mathrm{k} \Omega$ Internal Input Pulldown Resistors
- >2000V ESD Protection
- VEE Range of -3.0 V to -5.5 V

Note for PECL operation, the $\mathrm{V}_{\mathrm{CMR}}(\mathrm{min})$ will be fixed at $5.0 \mathrm{~V}-\left|\mathrm{V}_{\mathrm{CMR}}(\mathrm{min})\right|$.

## Differential Receiver

The MC100LVEL16 is a differential receiver. The device is functionally equivalent to the EL16 device, operating from a low voltage supply. The LVEL16 exhibits a wider CMR range than its EL16 counterpart. With output transition times and propagation delays comparable to the EL16 the LVEL16 is ideally suited for interfacing with high frequency sources at 3.3 V supplies.

The LVEL16 provides a $V_{B B}$ output for either single-ended use or as a $D C$ bias for $A C$ coupling to the device. The $V_{B B}$ pin should be used only as a bias for the LVEL16 as its current sink/source capability is limited. Whenever used, the $V_{B B}$ pin should be bypassed to ground via a $0.01 \mu \mathrm{f}$ capacitor.

Under open input conditions, the Q input will be pulled down to $\mathrm{V}_{\mathrm{ee}}$ and the $Q$ input will be biased to $\mathrm{V}_{\mathrm{CC}} / 2$. This condition will force the Q output low.

- 300ps Propagation Delay
- High Bandwidth Output Transitions
- $75 \mathrm{k} \Omega$ Internal Input Pulldown Resistors
- >2000V ESD Protection

1. Duty cycle skew is the difference between a TPLH and TPHL propagation delay through a device.
2. Minimum input swing for which AC parameters guaranteed. The device has a DC gain of $\approx 40$.
3. The CMR range is referenced to the most positive side of the differential input signal. Normal operation is obtained if the HIGH level falls within the specified range and the peak-to-peak voltage lies between VPpmin and 1 V . The lower end of the CMR range varies $1: 1$ with $\mathrm{V}_{\mathrm{EE}}$. The numbers in the spec table assume a nominal $V_{E E}=-3.3 \mathrm{~V}$. Note for PECL operation, the $\mathrm{V}_{\mathrm{CMR}}(\mathrm{min})$ will be fixed at $3.3 \mathrm{~V}-\left|\mathrm{V}_{\mathrm{CMR}}(\mathrm{min})\right|$.

## Low-Voltage Quad Differential Receiver

The MC100LVEL17 is a low-voltage, quad differential receiver. The device is functionally equivalent to the E116 device with the capability of operation from either a -3.3 V or +3.3 V supply voltage. The MC100EL17 is pin and functionally equivalent to the MC100LVEL17, but is specified for operation at the standard 100E ECL voltage supply.

The LVEL17 provides a $\mathrm{V}_{\mathrm{BB}}$ output for either single-ended use or as a DC bias for AC coupling to the device. The $\mathrm{V}_{\mathrm{BB}}$ pin should be used only as a bias for the LVEL17 as its current sink/source capability is limited. Whenever used, the $V_{B B}$ pin should be bypassed to ground via a $0.01 \mu \mathrm{f}$ capacitor.

Under open input conditions, the $\overline{\mathrm{D}}$ input will be biased at $\mathrm{V}_{\mathrm{CC}} / 2$ and the $D$ input will be pulled down to $V_{E E}$. This operation will force the $Q$ output LOW and ensure stability.

- 325ps Propagation Delay
- High Bandwidth Output Transitions
- >2000V ESD Protection
- Operates from $-3.3 /-4.5 \mathrm{~V}$ (or +3.3/+5.0V) Supply

## Dual Differential Data and Clock D Flip-Flop With Set and Reset

The MC100LVEL29 is a dual master-slave flip flop. The device features fully differential Data and Clock inputs as well as outputs. The MC100EL29 is pin and functionally equivalent to the MC100LVEL29 but is specified for operation at the standard 100E ECL voltage supply. A $V_{B B}$ output is provided for AC coupling, refer to the interfacing section of the ECLinPS Data Book (DL140) for more information on AC coupling ECL signals. Data enters the master latch when the clock is LOW and transfers to the slave upon a positive transition on the clock input.

The differential inputs have special circuitry which ensures device stability under open input conditions. When both differential inputs are left open the $D$ input will pull down to $V_{E E}$ and the $D$ input will bias around $\mathrm{V}_{\mathrm{CC}} / 2$. The outputs will go to a defined state, however the state will be random based on how the flip flop powers up.

Both flip flops feature asynchronous, overriding Set and Reset inputs. Note that the Set and Reset inputs cannot both be HIGH simultaneously.

- 1100 MHz Flip-Flop Toggle Frequency
- 20-lead SOIC Package
- 580ps Propagation Delays

1. The CMR range is referenced to the most positive side of the differential input signal. Normal operation is obtained if the HIGH level falls within the specified range and the peak-to-peak voltage lies between $V_{P P}$ min and 1 V . The lower end of the CMR range varies $1: 1$ with $\mathrm{V}_{\mathrm{EE}}$. The numbers in the spec table assume a nominal $\mathrm{V}_{\mathrm{EE}}=-4.5 \mathrm{~V}$. Note for PECL operation, the $\mathrm{V}_{\mathrm{CMR}}(\mathrm{min})$ will be fixed at $5.0 \mathrm{~V}-\left|\mathrm{V}_{\mathrm{CMR}}(\mathrm{min})\right|$.

## Triple D Flip-FIop <br> With Set and Reset

The MC100LVEL30 is a triple master-slave D flip flop with differential outputs. The MC100EL30 is pin and functionally equivalent to the MC100LVEL30 but is specified for operation at the standard 100E ECL voltage supply. Data enters the master latch when the clock input is LOW and transfers to the slave upon a positive transition on the clock input.

In addition to a common Set input individual Reset inputs are provided for each flip flop. Both the Set and Reset inputs function asynchronous and overriding with respect to the clock inputs.

- 1200 MHz Minimum Toggle Frequency
- 20-Lead SOIC Packaging
- 550ps Typical Propagation Delays
- Set and Reset Inputs
- Supports both Standard and Low Voltage 100K ECL
- Internal Input Pulldown Resistors
- >2000V ESD Protection

## Product Preview <br> $\div 2$ Divider

The MC100LVEL32 is an integrated $\div 2$ divider. The differential clock inputs and the $\mathrm{V}_{\mathrm{BB}}$ allow a differential, single-ended or AC coupled interface to the device. If used, the $\mathrm{V}_{\mathrm{BB}}$ output should be bypassed to ground with a $0.01 \mu \mathrm{~F}$ capacitor. Also note that the $\mathrm{V}_{\mathrm{BB}}$ is designed to be used as an input bias on the LVEL32 only, the $\mathrm{V}_{\mathrm{BB}}$ output has limited current sink and source capability.The LVEL32 is functionally identical to the EL32, but operates from a low voltage supply.

The reset pin is asynchronous and is asserted on the rising edge. Upon power-up, the internal flip-flop will attain a random state; the reset allows for the synchronization of multiple EL32's in a system.

- 510ps Propagation Delay
- 3.0 GHz Toggle Frequency
- High Bandwidth Output Transitions
- $75 \mathrm{k} \Omega$ Internal Input Pulldown Resistors
- >1000V ESD Protection

## $\div \mathbf{2} \div \mathbf{4} / \mathbf{6}$ Clock Generation Chip

The MC100LVEL38 is a low skew $\div 2, \div 4 / 6$ clock generation chip designed explicitly for low skew clock generation applications. The MC100EL38 is pin and functionally equivalent to the MC100LVEL38 but is specified for operation at the standard 100K ECL voltage supply. The internal dividers are synchronous to each other, therefore, the common output edges are all precisely aligned. The device can be driven by either a differential or single-ended LVECL or, if positive power supplies are used, LVPECL input signal. In addition, by using the $V_{B B}$ output, a sinusoidal source can be AC coupled into the device (see Interfacing section of the ECLinPSTM Data Book DL140/D). If a single-ended input is to be used, the $\mathrm{V}_{\mathrm{BB}}$ output should be connected to the CLK input and bypassed to ground via a $0.01 \mu \mathrm{~F}$ capacitor. The $\mathrm{V}_{\mathrm{BB}}$ output is designed to act as the switching reference for the input of the LVEL38 under single-ended input conditions, as a result, this pin can only source/sink up to 0.5 mA of current.

The common enable (EN) is synchronous so that the internal dividers will only be enabled/disabled when the internal clock is already in the LOW state. This avoids any chance of generating a runt clock pulse on the internal clock when the device is enabled/disabled as can happen with an asynchronous control. An internal runt pulse could lead to losing synchronization between the internal divider stages. The internal enable flip-flop is clocked on the falling edge of the input clock, therefore, all associated specification limits are referenced to the negative edge of the clock input.

The Phase_Out output will go HIGH for one clock cycle whenever the $\div 2$ and the $\div 4 / 6$ outputs are both transitioning from a LOW to a HIGH. This output allows for clock synchronization within the system.

Upon startup, the internal flip-flops will attain a random state; therefore, for systems which utilize multiple LVEL38s, the master reset (MR) input must be asserted to ensure synchronization. For systems which only use one LVEL38, the MR pin need not be exercised as the internal divider design ensures synchronization between the $\div 2$ and the $\div 4 / 6$ outputs of a single device.

- 50ps Output-to-Output Skew
- Synchronous Enable/Disable
- Master Reset for Synchronization
- $75 \mathrm{k} \Omega$ Internal Input Pulldown Resistors
- >1500V ESD Protection
- Low Voltage $\mathrm{V}_{\mathrm{EE}}$ Range of -3.0 to -3.8 V

## $\div 2 / 4, \div 4 / 6$ Clock <br> Generation Chip

The MC100LVEL39 is a low skew $\div 2 / 4, \div 4 / 6$ clock generation chip designed explicitly for low skew clock generation applications. The MC100EL39 is pin and functionally equivalent to the MC100LVEL39 but is specified for operation at the standard 100K ECL voltage supply. The internal dividers are synchronous to each other, therefore, the common output edges are all precisely aligned. The device can be driven by either a differential or single-ended LVECL or, if positive power supplies are used, LVPECL input signal. In addition, by using the VBB output, a sinusoidal source can be AC coupled into the device (see Interfacing section of the ECLinPS ${ }^{\text {TM }}$ Data Book DL140/D). If a single-ended input is to be used, the $\mathrm{V}_{\mathrm{BB}}$ output should be connected to the CLK input and bypassed to ground via a $0.01 \mu \mathrm{~F}$ capacitor. The $\mathrm{V}_{\mathrm{BB}}$ output is designed to act as the switching reference for the input of the LVEL39 under single-ended input conditions, as a result, this pin can only source/sink up to 0.5 mA of current.

The common enable (EN) is synchronous so that the internal dividers will only be enabled/disabled when the internal clock is already in the LOW state. This avoids any chance of generating a runt clock pulse on the internal clock when the device is enabled/disabled as can happen with an asynchronous control. An internal runt pulse could lead to losing synchronization between the internal divider stages. The internal enable flip-flop is clocked on the falling edge of the input clock, therefore, all associated specification limits are referenced to the negative edge of the clock input.

Upon startup, the internal flip-flops will attain a random state; therefore, for systems which utilize multiple LVEL39s, the master reset (MR) input must be asserted to ensure synchronization. For systems which only use one LVEL39, the MR pin need not be exercised as the internal divider design ensures synchronization between the $\div 2 / 4$ and the $\div 4 / 6$ outputs of a single device.

- 50ps Output-to-Output Skew
- Synchronous Enable/Disable
- Master Reset for Synchronization
- $75 \mathrm{k} \Omega$ Internal Input Pulldown Resistors
- >2000V ESD Protection
- Low Voltage VEE Range of -3.0 to -3.8 V

Pinout: 20-Lead SOIC (Top View)

1. Skew is measured between outputs under identical transitions.
2. Minimum input swing for which AC parameters are guaranteed. The device will function reliably with differential inputs down to 100 mV .
3. The CMR range is referenced to the most positive side of the differential input signal. Normal operation is obtained if the HIGH level falls within the specified range and the peak-to-peak voltage lies between $\mathrm{V}_{\mathrm{Pp}}$ min and 1 V . The lower end of the CMR range varies $1: 1$ with $\mathrm{V}_{\mathrm{EE}}$. The numbers in the spec table assume a nominal $\mathrm{V}_{\mathrm{EE}}=-3.3 \mathrm{~V}$. Note for PECL operation, the $\mathrm{V}_{\mathrm{CMR}}(\mathrm{min})$ will be fixed at $3.3 \mathrm{~V}-\left|\mathrm{V}_{\mathrm{CMR}}(\mathrm{min})\right|$.

1. Skew is measured between outputs under identical transitions.
2. Minimum input swing for which AC parameters are guaranteed. The device will function reliably with differential inputs down to 100 mV .
3. The CMR range is referenced to the most positive side of the differential input signal. Normal operation is obtained if the HIGH level falls within the specified range and the peak-to-peak voltage lies between $\mathrm{V}_{\mathrm{PP}}$ min and 1 V . The lower end of the CMR range varies $1: 1$ with $\mathrm{V}_{\mathrm{EE}}$. The numbers in the spec table assume a nominal $\mathrm{V}_{\mathrm{EE}}=-4.5 \mathrm{~V}$. Note for PECL operation, the $\mathrm{V}_{\mathrm{CMR}}(\mathrm{min})$ will be fixed at $5.0 \mathrm{~V}-\left|\mathrm{V}_{\mathrm{CMR}}(\mathrm{min})\right|$.

## Product Preview Differential Clock D Flip-Flop

The MC100LVEL51 is a differential clock D flip-flop with reset. The device is functionally equivalent to the EL51 device, but operates from a low voltage supply. With propagation delays and output transition times essentaially equal to the EL51, the LVEL51 is ideally suited for those applications which require the ultimate in AC performance at $3.3 \mathrm{~V} \mathrm{~V}_{\mathrm{CC}}$.

The reset input is an asynchronous, level triggered signal. Data enters the master portion of the flip-flop when the clock is LOW and is transferred to the slave, and thus the outputs, upon a positive transition of the clock. The differential clock inputs of the LVEL51 allow the device to be used as a negative edge triggered flip-flop.

The differential input employs clamp circuitry to maintain stability under open input conditions. When left open, the CLK input will be pulled down to $\mathrm{V}_{\mathrm{EE}}$ and the CLK input will be biased at $\mathrm{V}_{\mathrm{CC}} / 2$.

- 475ps Propagation Delay
- 2.8 GHz Toggle Frequency
- $75 \mathrm{k} \Omega$ Internal Input Pulldown Resistors
- >1000V ESD Protection

## Dual Differential 2:1 Multiplexer

The MC100LVEL56 is a dual, fully differential 2:1 multiplexer. The MC100EL56 is pin and functionally equivalent to the MC100LVEL56 but is specified for operation at the standard 100E ECL voltage supply. The differential data path makes the device ideal for multiplexing low skew clock or other skew sensitive signals. Multiple VBB pins are provided to ease AC coupling input signals (for more information on AC coupling ECL signals refer to the interfacing section of the ECLinPS data book DL140/D).

The device features both individual and common select inputs to address both data path and random logic applications.

The differential inputs have special circuitry which ensures device stability under open input conditions. When both differential inputs are left open the D input will pull down to $\mathrm{V}_{\mathrm{EE}}$, The D input will bias around $\mathrm{V}_{\mathrm{CC}} / 2$ forcing the Q output LOW.

- Differential Inputs and Outputs
- 20-Lead SOIC Packaging
- 440ps Typical Propagation Delays
- Separate and Common Select
- Supports Both Standard and Low Voltage 100K ECL
- Internal Input Pulldowns
- >2000V ESD Protection

## Triple 2:1 Multiplexer

The MC100LVEL59 is a triple 2:1 multiplexer with differential outputs. The MC100EL59 is pin and functionally equivalent to the MC100LVEL59 but is specified for operation at the standard 100E ECL voltage supply. The output data of the muxes can be controlled individually via the select inputs or as a group via the common select input. The flexibile selection scheme makes the device useful for both data path and random logic applications.

- Individual or Common Select Controls
- 20-Lead SOIC Packaging
- 500ps Typical Propagation Delays
- Supports Both Standard and Low Voltage 100K ECL
- Internal Input Pulldown Resistors
- >2000V ESD Protection

## Triple ECL to PECL Translator

The MC100LVEL/EL90 is a triple ECL to PECL translator. The device receives either standard or low voltage differential ECL signals and translates them to either standard or low voltage differential PECL output signals. The LVEL device can handle the low voltage signals while the EL device is designed for the standard signals. It is possible to have low voltage signals on one side and standard signals on the other if the LVEL90 is used.

- 500ps Propagation Delays
- Fully Differential Design
- Supports both Standard and Low Voltage Operation
- 20-Lead SOIC Packaging
$A V_{B B}$ output is provided for interfacing with single ended $E C L$ signals at the input. If a single ended input is to be used the $V_{B B}$ output should be connected to the D input. The active signal would then drive the D input. When used the $V_{B B}$ output should be bypassed to ground via a $0.01 \mu \mathrm{~F}$ capacitor. The $V_{B B}$ output is designed to act as the switching reference for the EL90 under single ended input switching conditions, as a result this pin can only source/sink up to 0.5 mA of current.

To accomplish the level translation the EL/LVEL90 requires three power rails. The $\mathrm{V}_{\mathrm{CC}}$ supply should be connected to the positive supply, and the $\mathrm{V}_{\mathrm{EE}}$ pin should be connected to the negative power supply. The GND pins as expected are connected to the system ground plain. Both $\mathrm{V}_{\text {EE }}$ and $\mathrm{V}_{\mathrm{CC}}$ should be bypassed to ground via $0.01 \mu \mathrm{~F}$ capacitors.

Under open input conditions, the $\overline{\mathrm{D}}$ input will be biased at $\mathrm{V}_{\mathrm{EE}} / 2$ and the $D$ input will be pulled to $V_{E E}$. This condition will force the Q output to a LOW, ensuring stability.

## Product Preview <br> Triple PECL to ECL Translator

The MC100LVEL/EL91 is a triple PECL to ECL translator. The device receives either standard or low voltage differential PECL signals and translates them to either standard or low voltage differential ECL output signals. The LVEL device can handle the low voltage signals while the EL device is designed for the standard signals. It is possible to have low voltage signals on one side and standard signals on the other if the LVEL91 is used.

- 550ps Propagation Delays
- Fully Differential Design
- Supports both Standard and Low Voltage Operation
- 20-lead SOIC Packaging
$\mathrm{A} \mathrm{V}_{\mathrm{BB}}$ output is provided for interfacing with single ended PECL signals at the input. If a single ended input is to be used the $V_{B B}$ output should be connected to the $D$ input. The active signal would then drive the $D$ input. When used the $\mathrm{V}_{\mathrm{BB}}$ output should be bypassed to ground via a $0.01 \mu \mathrm{~F}$ capacitor. The $V_{B B}$ output is designed to act as the switching reference for the EL91 under single ended input switching conditions, as aresult this pin can only source/sink up to 0.5 mA of current.

To accomplish the level translation the EL/LVEL91 requires three power rails. The $\mathrm{V}_{\mathrm{CC}}$ supply should be connected to the positive supply, and the $\mathrm{V}_{\mathrm{EE}}$ pin should be connected to the negative power supply. The GND pins as expected are connected to the system ground plain. Both $\mathrm{V}_{\mathrm{EE}}$ and $\mathrm{V}_{\mathrm{CC}}$ should be bypassed to ground via $0.01 \mu \mathrm{~F}$ capacitors.

Under open input conditions, the $\overline{\mathrm{D}}$ input will be biased at $\mathrm{V}_{\mathrm{CC}} / 2$ and the D input will be pulled to GND. This condition will force the Q output to a low, ensuring stability.

## Triple PECL to LVPECL Translator

The MC100LVEL92 is a triple PECL to LVPECL translator. The device receives standard PECL signals and translates them to differential LVPECL output signals.

- 500ps Propagation Delays
- Fully Differential Design
- 20-Lead SOIC Package
- 5 V and 3.3V Supplies Required
- >1500V ESD

A PECL VBB output is provided for interfacing single ended PECL signals at the inputs. If a single ended PECL input is to be used the PECL $V_{B B}$ output should be connected to the $\bar{D}$ input and the active signal will drive the $D$ input. When used the PECL $V_{B B}$ should be bypassed to ground via a $0.01 \mu \mathrm{f}$ capacitor. The PECL $\mathrm{V}_{\mathrm{BB}}$ is designed to act as a switching reference for the MC100LVEL92 under single ended input conditions, as a result the pin can only source/sink 0.5 mA of current.

To accomplish the PECL to LVPECL level translation, the MC100LVEL92 requires three power rails. The VCC supply is to be connected to the standard PECL supply, the LVCC supply is to be connected to the LVPECL supply, and Ground is connected to the system ground plane. Both the $\mathrm{V}_{\mathrm{CC}}$ and LVCC should be bypassed to ground with a $0.01 \mu \mathrm{f}$ capacitor.

Under open input conditions, the $\overline{\mathrm{D}}$ input will be biased at a $\mathrm{V}_{\mathrm{CC}} / 2$ voltage level and the D input will be pulled to ground. This condition will force the " $Q$ " output low, ensuring stability.

## Design Guide \& Application Notes

# SECTION 1 System Basics 

## Power Supply Considerations

The following text gives a brief description of the requirements and recommendations for treatment of power supplies in an ECLinPS* system design. A more thorough narration on the general subject of power supplies can be found in the Motorola System Design Handbook.

## VCC Supply

As with all previous ECL families the ECLinPS logic family is designed to operate with negative power supplies; in other words with $\mathrm{V}_{\mathrm{CC}}$ connected to ground. However, ECLinPS circuits will work fine with positive power supplies as long as special care has been taken to ensure a stable, quiet $\mathrm{V}_{\mathrm{CC}}$ supply. For more detailed information about using positive supplies and ECL, designers are encouraged to refer to Application Note AN1406 on page 5-60. The output voltage levels for a positive supply system can be determined by simply subtracting the absolute value of the standard negative output levels from the desired $\mathrm{V}_{\mathrm{CC}}$.

To provide as small an AC impedance as possible, and minimize power bus IR drops, the $\mathrm{V}_{\mathrm{CC}}$ supply should have a dedicated power plane. By providing a full ground plane in the system the designer ensures that the current return path for the signal traveling down a transmission line does not encounter any major obstructions. It is imperative that the noise and voltage drops be as small as possible on the $\mathrm{V}_{\mathrm{CC}}$ plane as the internal switching references and output levels are all derived off of the $\mathrm{V}_{\mathrm{CC}}$ power rail. Thus, any perturbations on this rail could adversely affect the noise margins of a system.

## VEe Supply

To take advantage of increased logic density and temperature compensated outputs, many designers are building array options with both, temperature compensated output levels and $a-5.2 \mathrm{~V}$ VEE supply. To alleviate any problems with interfacing these arrays to ECLinPS 100E devices, Motorola has specified the operation of 100E devices to include the standard 10 H VEE voltage range. Moreover, because of the superior voltage compensation of the bias network, this guarantee comes without any changes in the DC or AC specification limits. With the availability of both 10 H and 100 K compatible devices in the ECLinPS family, there is generally no need to run 10E devices at 100 K voltage levels. If, however, this is desired, the 10E devices will function at 100 E VEE levels with, at worst, a small degradation in AC performance for a few devices due to soft saturation of the current source device.

Although both the 10E and 100E devices can tolerate variations in the $V_{E E}$ supply without any detrimental effects, it is recommended that the $\mathrm{V}_{\text {EE }}$ supply also have a dedicated powerplane. If this is not a feasible constraint, care should be
taken so that the IR drops of the $\mathrm{V}_{\text {EE }}$ bus do not create a $\mathrm{V}_{\mathrm{EE}}$ voltage outside of the specification range. To provide the switching currents resulting from stray capacitances and asymmetric loading, the VEE power supply in an ECL system needs to be bypassed. It is recommended that the $\mathrm{V}_{\mathrm{EE}}$ supply be bypassed at each device with an RF quality $0.01 \mu \mathrm{~F}$ capacitor to ground. In addition, the supply should also be bypassed to ground with a $1.0 \mu \mathrm{~F}-10 \mu \mathrm{~F}$ capacitor at the power inputs to a board. If a separate output termination plane is used the $\mathrm{V}_{\text {EE }}$ supply will be of a static nature as the output switching current will return to ground via the $\mathrm{V}_{\mathrm{T} T}$ supply, thus, the bypassing of every device may be on the conservative side. If the design is going to include a liberal use of serial or Thevenin equivalent termination schemes, a properly bypassed $\mathrm{V}_{\text {EE }}$ plane is essential.

## $\mathrm{V}_{\mathrm{TT}}$ Supply

The output edge rates of the ECLinPS family necessitate an almost exclusive use of controlled impedance transmission lines for system interconnect (the details of this claim will be discussed in a latter section). Thus, unless Thevenin equivalent termination schemes are going to be used, a $\mathrm{V}_{\mathrm{TT}}$ supply is a must in ECLinPS designs. The choice of using only Thevenin equivalent termination schemes to save a power supply should not be made lightly as the Thevenin scheme consumes up to ten times more power than the equivalent parallel termination to $\mathrm{a}-2.0 \mathrm{~V} \mathrm{~V}_{\mathrm{T} T}$ supply.

As was the case for the $V_{\text {EE }}$ supply, a dedicated power plane, liberally bypassed as described above, should be used for the $\mathrm{V}_{\mathrm{T} T}$ supply. In designs which rely heavily on parallel termination schemes the $\mathrm{V}_{\mathrm{T}}$ supply will be responsible for returning the switching current of the outputs to ground, therefore, a low AC impedance is a must. For bypassing, many SIP resistor packs have bypass capacitors integrated in their design to supply the necessary bypassing of the supply. The use of SIP resistors will be discussed more thoroughly in a later chapter.

## Handling of Unused Inputs and Outputs

## Unused Inputs

All ECLinPS devices have internal $50 \mathrm{k} \Omega-75 \mathrm{k} \Omega$ pulldown resistors connected to $\mathrm{V}_{\text {EE }}$. As a result, an input which is left open will be pulled to VEE and, thus, set at a logic LOW. These internal pulldowns provide more than enough noise margin to keep the input from turning on if noise is coupled to the input, therefore, there is no need to tie the inputs to $V_{E E}$ external to the package. In addition, by shorting the inputs to $V_{E E}$ external to the package, one removes the current limiting effect of the pulldown resistor and, under extreme $\mathrm{V}_{\mathrm{EE}}$

[^11]conditions, the input transistor could be permanently damaged. If there are concerns about leaving sensitive inputs, such as clocks, open, they should be tied low via an unused output or a quiet connection to VTT.

Unless otherwise noted on the data sheets, the outputs to differential input devices will go to a defined state when the inputs are left open. This is accomplished via an internal clamp. Note that this clamp will only take over if the voltage at the inputs fall below $\approx-2.5 \mathrm{~V}$. Therefore, if equal voltages of greater than -2.5 V are placed on the inputs, the outputs will attain an undefined midswing state.

Unlike saturating logic families, the inputs to an ECLinPS, or any ECL device, cannot be tied directly to VCC to implement a logic HIGH level. Tying inputs to $\mathrm{V}_{\mathrm{CC}}$ will saturate the input transistor and the AC and DC performance will be seriously impaired. A logic HIGH on an ECLinPS input should be tied to a level no higher than 600 mV below the $\mathrm{V}_{\mathrm{CC}}$ rail and, more typically, no higher than the specified $\mathrm{V}_{\mathrm{IH}}$ max limit. A resistor or diode tree can be used to generate a logic HIGH level or, more commonly, an output of an unused gate can be used.

## Unused Outputs

The handling of unused outputs is guided by two criteria: power dissipation and noise generation. For single ended output devices it is highly recommended to leave unused outputs unterminated as there are no benefits in the alternative scheme. This not only saves the power associated with the output, but also reduces the noise on the $\mathrm{V}_{\mathrm{CC}}$ line by reducing the current being switched through the inductance of the $\mathrm{V}_{\mathrm{CC}}$ pins. For the counters and shift registers of the family, the count and shift frequencies will be maximized if the parallel outputs are left unterminated. Of course, for applications where these parallel outputs are needed this is not a viable alternative.

For the differential outputs, on the other hand, things are a little less cut and dry. If either of the outputs of a complimentary output pair is being used, both outputs of the pair should be terminated. This termination scheme minimizes the current being switched through the $\mathrm{V}_{\mathrm{CC}}$ pin and, thus, minimizes the noise generated on $\mathrm{V}_{\mathrm{CC}}$. If, however, neither of the outputs of a complimentary pair are being used it makes most sense to leave these unterminated to save power. Note that the E111 device has special termination rules; these rules are outlined on the data sheet for the device.

## Minimizing Simultaneous Switching Noise

A common occurrence among ECL families is the generation of crosstalk and other noise phenomena during simultaneous switching situations. Although the noise generated in ECL systems is minor compared to other technologies, there are methods to even further minimize the problem.

Figure 1.1 below illustrates the two output scenarios of an ECL device: differential outputs and single-ended outputs. During switching, the current in the output device will change by $\approx 17 \mathrm{~mA}$ when loaded in the normal $50 \Omega$ to -2.0 V load. With differential outputs, as one output switches from a low to
a high state the other switches from a high to a low state simultaneously, thus, the resultant current change through the $\mathrm{V}_{\mathrm{CCO}}$ connection is zero. The current simply switches between the two outputs. However, for the single-ended output, the current change flows through the $\mathrm{V}_{\mathrm{CCO}}$ connection of the output device. This current change through the $\mathrm{V}_{\mathrm{CCO}}$ pin of the package causes a voltage spike due to the inductance of the pin.

Figure 1.1. ECL Output Structures
Traditionally, manufacturers of ECL products have attempted to combat this problem by providing a separate $\mathrm{V}_{\mathrm{CC}}$ pin for the output device ( $\mathrm{V}_{\mathrm{CCO}}, \mathrm{V}_{\mathrm{CCA}}$ etc.) and the internal circuitry. By doing this the noise generated on the $\mathrm{V}_{\mathrm{CCO}}$ of the output devices would see a high impedance internal to the chip and not couple onto the the $\mathrm{V}_{\mathrm{CC}}$ line which controls the output and internal bias levels. Unfortunately, in practice the noise generated on the $\mathrm{V}_{\mathrm{CCO}}$ would couple into the chip $\mathrm{V}_{\mathrm{C}}$ through the collector base capacitance of the output device, thus, a large portion of the noise seen on the $\mathrm{V}_{\mathrm{CCO}}$ line would also be seen on the $\mathrm{V}_{\mathrm{CC}}$ line.

For the ECLinPS family and its associated edge speeds, it was decided that multiple $\mathrm{V}_{\mathrm{CCO}}$ pins would be necessary to minimize the inductance and the associated noise generation. A design rule was established so that there would be no more than three single-ended outputs per $\mathrm{V}_{\mathrm{CCO}}$ pin. Initially, the $\mathrm{V}_{\mathrm{CC}}$ and $\mathrm{V}_{\mathrm{CCO}}$ pins were kept isolated from
one another. However, it was discovered that in certain applications the parasitics of the package and the output device would combine to produce an instability which resulted in the outputs going into an oscillatory state. To alleviate this oscillation problem, it was necessary to make the $\mathrm{V}_{\mathrm{CC}}$ and $\mathrm{V}_{\mathrm{CCO}}$ metal common internal to the package. Subsequent evaluation showed that because of the liberal use of $\mathrm{V}_{\mathrm{CCO}}$ pins, the noise generated is equal to or less than that of previous ECL families.

To further reduce the noise generated there are some things that can be done at the system level. As mentioned above, there should be adequate bypassing of the $\mathrm{V}_{\mathrm{CC}}$ line and the guidelines for the handling of unused outputs should be followed. In addition, for wide single-ended output devices, an increase in the characteristic impedance of the transmission line interconnect will result in a smaller time rate of change of current; thus, reducing the voltage glitch caused by the inductance of the package. This noise improvement should, of course, be weighed against the potential slowing of the higher impedance trace to optimize the performance of the entire system. In addition, the connection between the device $\mathrm{V}_{\mathrm{CC}}$ pins and the ground plane should be as small as possible to minimize the inductance of the $\mathrm{V}_{\mathrm{CC}}$ line. Note that a device mounted in a socket will exhibit a larger amount of $V_{\text {CC }}$ noise due to the added inductance of the socket pins.

## Effects of Capacitive Loads

The issue of $A C$ parametric shifts with load capacitance is a common concern especially with designers coming from the TTL and CMOS worlds. For ECLinPS type edge speeds, wire interconnect starts acting like transmission lines for lengths greater than $1 / 2^{\prime \prime}$. Therefore, for the majority of cases in ECLinPS designs, the load on an output is seen by the transmission line and not the output of the driving device. The effects of load capacitance on transmission lines will be discussed in detail in the next section.

If the load is close to the driving output $\left(<1 / 2^{\prime \prime}\right)$, the resulting degradation will be $15-25 \mathrm{ps} / \mathrm{pF}$ for both propagation delays and edge rates. In general, a capacitive load on an emitter follower has a greater impact on the falling edge than the rising edge. Therefore, the upper end of the range given above represents the effect on fall times and the associated propagation delays, while the lower end represents the effect on the rising output parameters.

For ECLinPS devices, the capacitive load produced by an input ranges from 1.2 pF to 2.0 pF . The majority ( $\approx 95 \%$ ) of this capacitance is contributed by the package with very little added by the internal input circuitry. For this reason the range is generally a result of the difference between a corner and a center pin for the PLCC package. A good typical capacitance value for a center pin is 1.4 pf and for a corner pin 1.7 pf . The capacitances for the other pins can be deduced through a linear interpolation.

## Wired-OR Connections

The use of wired-OR connections in ECL designs is a popular way to reduce total part count and optimize the speed performance of a system. The limitation of OR-tying

ECL outputs has always been a combination of increased delay per OR-tie and the negative going disturbance seen at the output when one output switches from a high to a low while the rest of the outputs remain high. For high speed devices the latter problem is the primary limitation due to the increased sensitivity to this phenomena with decreasing output transition times. The following paragraph will attempt to describe the wire-OR glitch phenomena from a physical perspective.

Figure 1.2 illustrates a typical wire-OR situation. For simplicity, the discussion will deal with only two outputs; however, the argument could easily be expanded to include any number of outputs. If both the A and the B outputs start in the high state they will both supply equal amounts of current to the load. If the $B$ output then transitions from a high to a low the line at the emitter of $B$ will see a sudden decrease in the line voltage. This negative going transition on the line will continue downward at the natural fall time of the output until the A output responds to the voltage change and supplies the needed current to the load. This lag in the time it takes for $A$ to correct the load current and return the line to a quiescent high level is comprised of three elements: the natural response time of the A output, the delay associated with the trace length between the two outputs and the time it takes for a signal to propagate through the package. The trace delay can be effectively forced to zero by OR-tying adjacent pins. The resulting situation can then be considered "best case". In this best case situation, if the delay through the package is not a significant portion of the transition time of the output, the resulting negative going glitch will be relatively small $(\approx 100 \mathrm{mV})$. A disturbance of this size will not propagate through a system. As the trace length between OR-tied outputs increases, the magnitude of the negative going disturbance will increase. Older ECL families specified the maximum delay allowed between OR-tied outputs to prevent the creation of a glitch which would propagate through a system.

As this glitch phenomena is a physical limitation, due to decreased edge rates, ECLinPS devices are susceptible to the problem to an even greater degree than previous slower ECL families. The package delay of even the 28-lead PLCC

Figure 1.2. Typical Wire-OR Configuration
is a significant portion of the transition times for an ECLinPS device. Therefore, even in the best case situation described above, one can expect an $\approx 200 \mathrm{mV}$ glitch on the OR-tied line. A glitch of this magnitude will not propagate through the system but it is significantly worse than the best case situation of earlier ECL families. In fact, as long as the distance between OR-tied outputs is kept to less than $1 / 2^{\prime \prime}$ the resulting line disturbance will not be sufficient to propagate through most systems.

With this in mind, the following recommendations are offered for OR-tying in ECLinPS designs. First, OR-tying of clock lines should be avoided as even in the best case situation the disturbance on the line is significant and could cause false clocking in some situations. In addition, wire ORed outputs should be from the same package and preferably should be adjacent pins. Non-adjacent outputs should be within $1 / 2^{\prime \prime}$ of each other with the load resistor connection situated near the midpoint of the trace (Figure 1.2). By following these guidelines, the practice of wire-ORing ECL outputs can be expanded to the ECLinPS family without encountering problems in the system.

A detailed discussion of wire-OR connections in the ECLinPS world of performance is beyond the scope of this text. For this reason a separate application note has been written which deals with this situation in a much more thorough manner. Anyone planning to use wire-OR connections in their ECLinPS design is encouraged to contact a Motorola representative to obtain this application note.

## Clock Distribution

Clock skew is a major contributor to the upper limit of operation of a high speed system; therefore, any reduction in this parameter will enhance the overall performance of a system. Through the ECLinPS family and new offerings in the 10 H family, Motorola is providing devices uniquely designed to meet the demands of low skew clock distribution.

By far the largest contributor to system skew is the variation between different process lots of a given device. This variation is what defines the total delay window specified in the data sheets. This window can be minimized if the devices are fully differential due to the output level defined thresholds which ensure a "centered" input swing. The propagation delay windows of single-ended ECL and other logic technologies, are intimately tied to variations in the input thresholds. As illustrated in Figure 1.3 although the delays, when measured from the threshold of the input to the 50\% point of the output, are equal; when measured from the specified $50 \%$ point of the input to the $50 \%$ point of the output, the delays will vary with any shift in the switching reference. Obviously, the magnitude of the delay difference is also proportional to the edge rate of the input. In addition to increasing the size of the delay windows, this reference shift will cause the duty cycle of the output of a device to be different than that of the input. Unfortunately, these thresholds are perhaps the most difficult aspects of a logic device to control. As a result, for the ultimate in low skew performance differential ECL devices are a must. A quick perusal of the ECLinPS databook will reveal a relatively large number of totally differential devices which will lend themselves nicely to very low skew applications such as clock distribution.

Figure 1.3. Delay vs Switching Reference Offset

In addition to these generic differential devices there are several devices which were designed exclusively for clock distribution systems. With past ECL families designers were forced to build clock distribution trees with devices which were compromises at best. The ECLinPS family, however, was built around the E111 clock distribution chip; a fully differential 1:9 fanout device which boasts within part skews as well as part- to-part skews unequaled in today's market.

Additionally, to further deskew clock lines the E195 programmable delay chip is available. Although static delay lines can remove built-in path length difference skew, they cannot compensate for variations in the delays of the devices in the clock path. The E195 allows the user to delay, a signal over a 2 ns range in $\approx 20 \mathrm{ps}$ steps. Through the use of this device, the designer can match skews between clocks to 20ps.

Although these two devices satisfy the needs for many ECL designers, they do overlook the needs of a special subset; the designer who mixes ECL and TTL technologies. When translating between ECL and TTL, much of the skew performance gained through the E111 is lost when passed through the translator and distributed in TTL. To solve this problem, a new set of translators has been introduced in the MECL 10H family. The H 641 and H 643 receive a differential ECL input and fan out nine TTL outputs with a guaranteed unparalleled skew between the TTL outputs. The H640 and H642 take differential ECL inputs and generate low skew TTL outputs which are ideal for driving clocks in 68030 and 68040 microprocessor systems. By using the ECL aspects of the E111 to distribute clock lines across the backplane to TTL cards and receiving and translating these signals with the H640, H641, H642 or H643, a TTL clock distribution tree can be designed with a performance level unheard of with past logic families.

## System Basics

Through the development of a library of differential devices, specialized low-skew distribution chips and high-resolution programmable delay chips, Motorola has serviced the need for low-skew clock distribution designs. These offerings open the door for even higher performance next generation machines. For more information on clock distribution, designers are encouraged to read Application Note AN1405 on page 5-53.

## Metastability Behavior

The metastability behavior and measurement of a flip-flop is a complicated subject and necessitates much more time than is available in this forum for a thorough explanation. As a result, the following description is of an overview nature. Anyone interested in a more thorough narration on the subject is encouraged to read Application Note AN1504 on page 5-79, which contains a more detailed discussion on the subject.

In many designs, occasions arise where an asynchronous signal needs to be synchronized to the system clock.

Generally, this task is accomplished with the use of a single or series of $D$ flip-flops as pictured in Figure 1.4. Because the data signal and the clock signal are asynchronous, the system designer cannot guarantee that the setup and hold specifications for the device will be met. This in and of itself would not cause a problem if it was not for the metastable behavior of a D flip-flop. The metastable behavior of a flip-flop is described by the outputs of a device attaining a nondefined logic level or, perhaps, going into an oscillatory state when the data and the clock inputs to the flip-flop switch simultaneously. It has been shown that this metastable behavior occurs across technology boundaries as well as across performance levels within a technology.

For ECL the characteristic of a flip-flop in a metastable state is a device whose outputs are in a non-defined state near the midpoint of a normal output swing. The output will return randomly to one of the two defined states some time later (Figure 1.5). The two parameters of importance when discussing metastability are the metastablity window; the window in time for which a transition on both the data and the

Figure 1.4. Clock Synchronization Schemes

Figure 1.5. Metastable Behavior of an ECL Flip Flop
clock will cause a metastable output, and the settling time; the time it takes for a metastable output to return to a defined state. For the single flip-flop design of Figure 1.3, the data being fed into system 2 will be in an undefined state and, thus, unusable if the synchronizing flip-flop enters a metastable state. Because of this, a more popular design incorporates multiple flip-flop chains with cascading data inputs and clock inputs which are delayed with respect to each other. This redundancy of flip- flops helps to reduce the probability that the data entering system 2 will be at an undefined level which could wreak havoc on the logic of that system. This reduction in probability relies on the fact that even if the preceding flip-flop goes metastable, it will settle to a defined state prior to the clocking of the following flip-flop. Obviously, once the first flip-flop goes metastable there is an even chance that it will settle in the wrong state and, thus, information will be lost. However, there are error detection and correction methods to circumvent this problem. The larger the flip-flop chain the lower the probability of metastable data being fed into system 2.

Unfortunately for ECLinPS, levels of performance, both the window width and the settling time, are difficult or impossible to measure directly. The metastable window for an ECLinPS flip-flop is assuredly less than 5.0ps and most likely less than 1.0 ps based on SPICE level simulation results. In either case, with today's measuring equipment, it would be impossible to measure this window width directly. Although it is feasible to measure the settling time for a given occurrence, this parameter is not fixed but, rather, is of a variable length which makes it impossible to provide an absolute guarantee.

The challenge then becomes, how to characterize metastability behavior given the above circumstances. The standard method in the industry is to use Stoll's ${ }^{1}$ equation, combined with the standard MTBF equation, to develop the following relationship:

MTBF $=1 /\left(2^{*} f C^{* f} D^{*} T P^{* 10-(t / \tau)}\right)$
where:

| $\mathrm{f}_{\mathrm{C}}:$ | Clock Frequency |
| :--- | :--- |
| $\mathrm{fD}_{\mathrm{D}}:$ | Data Frequency |
| $\mathrm{T}_{\mathrm{p}}:$ | FF Propagation Delay |
| $\mathrm{t}:$ | Time Delay Between FF |

Clocks
Constant
Note that the clock frequency, data frequency and time delay between flip-flops are user-defined parameters, thus it is up to Motorola to provide only the propagation delays and the resolution time constants for the ECLinPS flip-flops.

The propagation delays are, obviously, already defined leaving only the resolution time constant yet to be determined. An evaluation fixture was fabricated and several ECLinPS flip-flops were evaluated for resolution time constants. The results of the evaluation showed that the time constant was somewhat dependent on the part type as all the flip-flops in the ECLinPS family do not use the same general design. The time constants range from 125-225 ps depending on the part type.

As an example, for a system with a 100 MHz clock and 75 MHz data rate, the required delay between clock edges of a cascaded flip-flop chain for the E151 register, assuming a $\tau$ of 200 ps , would be:

MTBF $=1 /\left(2^{*} 100 \mathrm{MHz}^{*} 75 \mathrm{MHz}^{*} 800 \mathrm{ps}^{*} 10-\mathrm{t} / 200 \mathrm{ps}\right)$
solving for an MTBF of 10 years yields:
$\mathrm{t}=3.1 \mathrm{~ns}$, therefore:
$T D=\Delta t+T P=3.9 n s$
So, for an MTBF of 10 years for the above situation the second flip-flop should be clocked 3.9 ns after the first. Similar results can be found by applying the equation to different data and clock rates as well as different acceptable MTBF rates.

VLSI Design, November/December 1982. pp. 56-59.

# SECTION 2 <br> Transmission Line Theory 

## Introduction

The ECLinPS family has pushed the world of ECL into the realm of picoseconds. When output transitions move into this picosecond region it becomes necessary to analyze system interconnects to determine if transmission line phenomena will occur. A handy rule of thumb to determine if an interconnect trace should be considered a transmission line is if the interconnect delay is greater than $1 / 8$ th of the signal transition time, it should be considered a transmission line and afforded all of the attention required by a transmission line. If this rule is applied to the ECLinPS product line a typical PCB trace will attain transmission line behaviors for any length $>1 / 4^{\prime \prime}$. Thus, a brief overview of transmission line theory is presented, including a discussion of distributed and lumped capacitance effects on transmission lines. For a more thorough discussion of transmission lines the reader is referred to Motorola's MECL Systems Design Handbook.

## Background

Exact transmission line analysis can be both tedious and time consuming; therefore, assumptions for simplifying these types of calculations must be made. A reasonable assumption is that interconnect losses caused by factors such as bandwidth limitations, attenuation, and distortion are negligible for a typical PCB trace. The basis for this assumption is that losses due to the interconnect conductor are only a fraction of the total losses in the entire interface scheme. In addition, the conductivity of insulating material is very small; as a result, the dielectric losses are minimal. A second, and more fundamental, assumption is that transmission line behavior can be described by two parameters: line characteristic impedance (ZO), and propagation delay (TPD)

## Characteristic Impedance

An interconnect which consists of two conductors and a dielectric, characterized by distributed series resistances and inductances along with distributed parallel capacitances between them, is defined as a transmission line. These transmission lines exhibit a characteristic impedance over any length for which the distributed parameters are constant. Since the contribution of the distributed series resistance to the overall impedance is minimal, this term can be neglected when expressing the characteristic impedance of a line. The characteristic impedance is a dynamic quantity defined as the ratio of the transient voltage to the transient current passing through a point on the line. Thus, $\mathrm{Z}_{\mathrm{O}}$ can be expressed in terms of the distributed inductance and capacitance of the line as shown by Equation 1.
$\mathrm{Z}_{\mathrm{O}}=\mathrm{V} / \mathrm{I}=\sqrt{ }\left(\mathrm{L}_{\mathrm{O}} / \mathrm{C}_{\mathrm{O}}\right)$
(Equation 1)
where:
$\mathrm{L}_{\mathrm{O}}=$ Inductance per unit length $(\mathrm{H})$
$\mathrm{C}_{\mathrm{O}}=$ Capacitance per unit length (F)

## Propagation Delay

Propagation delay (TPD) is also expressed as a function of both the inductance and capacitance per unit length of a transmission line. The propagation delay of the line is defined by the following equation:

$$
\mathrm{T} P \mathrm{D}=\sqrt{ }\left(\mathrm{L}_{\mathrm{O}} * \mathrm{CO}\right)
$$

(Equation 2)
If $L_{O}$ is expressed as microHenry's per unit length and capacitance as picoFarad's per unit length, the units for delay are nanoseconds per unit length. The propagation velocity is defined as the reciprocal of the propagation delay:

$$
v=1 / T_{P D}=1 / \sqrt{ }\left(L_{O}{ }^{*} C_{O}\right)
$$

$\mathrm{L}_{\mathrm{O}}$ and $\mathrm{C}_{\mathrm{O}}$ can be determined using the easily measured parameters of line delay (TD), line length (L), and the line characteristic impedance ( $\mathrm{Z}_{\mathrm{O}}$ ) in conjunction with Equations 1 and 2. The propagation delay is defined as the ratio of line delay to line length:

```
TPD=TD/L
```

Combining equations 1 and 2 yields:

$$
\begin{align*}
& \mathrm{CO}=\mathrm{TPD}^{\prime} \mathrm{ZO}_{\mathrm{O}}  \tag{Equation3}\\
& \mathrm{~L}_{\mathrm{O}}=\mathrm{TPD}^{*} \mathrm{O}_{\mathrm{O}}
\end{align*}
$$

(Equation 4)

## Termination and Reflection Theory

Figure 2.1 shows an ECLinPS gate driving a lossless transmission line of characteristic impedance $\mathrm{Z}_{\mathrm{O}}$, and terminated with resistance $\mathrm{R}^{\mathrm{T}}$. Modifying the circuit of Figure 2.1 such that the driving gate is represented by its equivalent circuit gives the configuration shown in Figure 2.2.

For a positive step function $\mathrm{V}_{\mathrm{IN}}$, a voltage step $\mathrm{V}_{\mathrm{S}}$, travels down the transmission line. The initial current in the transmission line is determined by the ratio $\mathrm{V}_{\mathrm{S}} / \mathrm{Z}_{\mathrm{O}}$. When the traveling wave arrives at the termination resistor $\mathrm{R} T$, Ohm's

Figure 2.1. Typical Transmission Line Driving Scenario

Law must be maintained. If the line characteristic impedance and the termination resistance match (i.e. $\mathrm{Z}_{\mathrm{O}}=\mathrm{R}_{\mathrm{T}}$ ), the traveling wave does not encounter a discontinuity at the line-load interface; thus, the total voltage across the termination resistance is the incident voltage $\mathrm{V}_{\mathrm{S}}$. However, if mismatches between the line characteristic impedance and the termination resistance occur, a reflected wave must be set up to ensure Ohm's Law is obeyed at the line-load interface. In addition, the reflected wave may also encounter a discontinuity at the interface between the transmission line and the source resistance, thereby sending a re-reflected wave back towards the load. When neither the source nor the load impedance match the line characteristic impedance multiple reflections occur with the reflected signals being attenuated with each passage over the transmission line. The output response of this configuration appears as a damped oscillation, asymptotically approaching the steady state value, a phenomenon often referred to as ringing.

Figure 2.2. Thevenin Equivalent Circuit of Figure 2.1

In performing transmission line analysis, designers may encounter one of three impedance situations:

1. $\mathrm{R}_{\mathrm{S}}<\mathrm{Z}_{\mathrm{O}} ; \mathrm{R}_{\mathrm{T}} \neq \mathrm{Z}_{\mathrm{O}}$
2. $\mathrm{R}_{\mathrm{S}} \leq \mathrm{Z}_{\mathrm{O}} ; \mathrm{R}_{\mathrm{T}}=\mathrm{Z}_{\mathrm{O}}$
3. $R_{S}=Z_{O} ; R_{T} \neq Z_{O}$
where:
Rs
= Source Resistance
RT = Termination Resistance

## Case 1: $\mathbf{R s}_{\mathbf{S}}<\mathrm{Z}_{\mathbf{O}} ; \mathrm{R}_{\mathbf{T}} \neq \mathbf{Z}_{\mathbf{O}}$

The initial current in the transmission line is determined by the ratio $\mathrm{V}_{\mathrm{S}} / \mathrm{Z}_{\mathrm{O}}$. However, the final steady state current is determined by the ratio $\mathrm{V}_{\mathrm{S}} / \mathrm{R}_{\mathrm{T}}$, assuming ohmic losses in the transmission line are negligible. For case 1, an impedance discontinuity exists at the line-load interface which causes a reflected voltage and current to be generated at the instant the initial signal arrives at this interface. To determine the fraction of the traveling wave that will be reflected from the line-load interface, Kirchoff's current law is applied to node "a" in Figure 2.2. This results in the following:
$I_{T}=I_{S}+I_{R}$ where:
$\mathrm{I}_{\mathrm{T}}=\mathrm{V}_{\mathrm{T}} / \mathrm{R}_{\mathrm{T}}$

$$
\begin{aligned}
& \mathrm{I}_{\mathrm{S}}=\mathrm{V}_{\mathrm{S}} / \mathrm{Z}_{\mathrm{O}} \\
& \mathrm{I}_{\mathrm{R}}=-\mathrm{V}_{\mathrm{R}} / \mathrm{Z}_{\mathrm{O}}
\end{aligned}
$$

Using substitution:

$$
\mathrm{V}_{\mathrm{T}} / \mathrm{R}_{\mathrm{T}}=\mathrm{V}_{\mathrm{S}} / \mathrm{Z}_{\mathrm{O}}-\mathrm{V}_{\mathrm{R}} / \mathrm{Z}_{\mathrm{O}}
$$

Since only one voltage can exist at node "a" at any instant in time:

$$
\begin{equation*}
\mathrm{V}_{\mathrm{T}}=\mathrm{V}_{\mathrm{S}}+\mathrm{V}_{\mathrm{R}} \tag{Equation6}
\end{equation*}
$$

Combining Equations 5 and 6 , and solving for $\mathrm{V}_{\mathrm{R}}$ yields:

$$
\begin{aligned}
& \left(\mathrm{V}_{\mathrm{S}}+\mathrm{V}_{\mathrm{R}}\right) / \mathrm{R}_{\mathrm{T}}=\mathrm{V}_{\mathrm{S}} / \mathrm{Z}_{\mathrm{O}}-\mathrm{V}_{\mathrm{R}} / \mathrm{Z}_{\mathrm{O}} \\
& \mathrm{~V}_{\mathrm{R}}=\left(\left(\mathrm{R}_{\mathrm{T}}-\mathrm{Z}_{\mathrm{O}}\right) /\left(\mathrm{R}_{\mathrm{T}}+\mathrm{Z}_{\mathrm{O}}\right)\right)^{*} \mathrm{~V}_{\mathrm{S}} \\
& \mathrm{~V}_{\mathrm{R}} / \mathrm{V}_{\mathrm{S}}=\rho_{\mathrm{L}}=\left(\mathrm{R}_{\mathrm{T}}-\mathrm{Z}_{\mathrm{O}}\right) /\left(\mathrm{R}_{\mathrm{T}}+\mathrm{Z}_{\mathrm{O}}\right)
\end{aligned}
$$

(Equation 7)

Therefore:
$V_{R}=\rho_{L}{ }^{*} V_{S}$
The term $\rho_{\mathrm{L}}$ referred to as the load reflection coefficient, represents the fraction of the voltage wave arriving at the lineload interface that is reflected back toward the source.

Similarly, a source reflection coefficient can be derived as:

$$
\begin{equation*}
\rho_{S}=\left(R_{S}-Z_{O}\right) /\left(R_{S}+Z_{O}\right) \tag{Equation8}
\end{equation*}
$$

From equations 7 and 8 it is apparent that multiple reflections will occur when neither the source nor the load impedances match the characteristic impedance of the line. A general equation for the total line voltage as a function of time and distance is expressed by Equation 9.
where:

$\mathrm{V}_{\mathrm{A}}=$ Voltage Entering the Transmission Line
TPD = Propagation Delay of the Line
L = Total Line Length
$x \quad=$ Distance to an Arbitrary Point on the Line
VDC = Initial Quiescent Voltage of the Line
Finally, the output voltage, $\mathrm{V}_{\mathrm{T}}$ can be derived from the reflection coefficient by combining Equations 6 and 7:

$$
\begin{aligned}
& \mathrm{V}_{\mathrm{T}}=\left(1+\left(\mathrm{R}_{\mathrm{T}}-\mathrm{Z}_{\mathrm{O}}\right) /\left(\mathrm{R}_{\mathrm{T}}+\mathrm{Z}_{\mathrm{O}}\right)\right)^{*} \mathrm{~V}_{\mathrm{S}} \\
& \mathrm{~V}_{\mathrm{T}}=\left(2^{*} \mathrm{R}_{\mathrm{T}} /\left(\mathrm{R}_{\mathrm{T}}+\mathrm{Z}_{\mathrm{O}}\right)\right)^{*} \mathrm{~V}_{\mathrm{S}}
\end{aligned}
$$

The two possible configurations for the Case 1 conditions are $\mathrm{R}_{\mathrm{T}}>\mathrm{Z}_{\mathrm{O}}$ and $\mathrm{R}_{\mathrm{T}}<\mathrm{Z}_{\mathrm{O}}$. The following paragraphs will describe these two conditions in detail.

$$
\begin{aligned}
& \mathrm{V}(\mathrm{x}, \mathrm{t}) \quad \mathrm{V}_{\mathrm{A}}(\mathrm{t})^{*}\left[\mathrm{U}\left(\mathrm{t}-\mathrm{TPD}^{*} \mathrm{x}\right)+\rho_{\mathrm{L}^{*}} \mathrm{U}(\mathrm{t}-\mathrm{T} P \mathrm{P}(2 \mathrm{~L}-\mathrm{x})+\right. \\
& \rho_{L}{ }^{*} \rho_{S}{ }^{*} U(t-T P D(2 L+x))+ \\
& \left(\rho_{L}^{* *}\right)^{*}\left(\rho_{S}{ }^{*} \mathrm{U}(\mathrm{t}-\mathrm{TPD}(4 \mathrm{~L}-\mathrm{x}))+\right. \\
& \left.\left.\left(\rho_{\mathrm{L}}{ }^{* *} 2\right)^{*} \rho_{\mathrm{S}}{ }^{* *} 2\right)^{*} \mathrm{U}(\mathrm{t}-\mathrm{TPD}(4 \mathrm{~L}+\mathrm{x}))+\ldots\right]+ \\
& V_{D C} \\
& \text { (Equation 9) }
\end{aligned}
$$

Configuration 1: $R_{T}>Z_{O}$
For the case in which $\mathrm{R}_{\mathrm{T}}>\mathrm{Z}_{\mathrm{O}}, \rho_{\mathrm{L}}$ is positive, and the initial current at node "a" is greater than the final quiescent current:

IINITIAL $>$ IFINAL

Hence:

$$
\left.\mathrm{V}_{\mathrm{S}} / \mathrm{Z}_{\mathrm{O}}\right)>\left(\mathrm{V}_{\mathrm{S}} / \mathrm{R}_{\mathrm{T}}\right)
$$

Thus, a reflected current, IR, must flow toward the source in order to attain the final steady state current as shown in Figure 2.3.

An example of a line mismatched at both ends, with the termination resistance greater than the load resistance is shown

Figure 2.3. Reflected Voltage Wave for $\mathrm{R}_{\boldsymbol{T}}>\mathrm{Z}_{\mathbf{O}}$
in Figure 2.4. The initial steady state output voltage is given by:

$$
\mathrm{V}_{\mathrm{TI}}=(65 / 71)^{*}(-1.75)=-1.60 \mathrm{~V}
$$

The final steady state output voltage is given by:

Figure 2.4. Transmission Line Model for $\mathrm{R}_{\boldsymbol{T}}>\mathrm{Z}_{\mathbf{O}}$

$$
\mathrm{V}_{\mathrm{TF}}=(65 / 71)^{*}(-0.9)=-0.82 \mathrm{~V}
$$

The input voltage is a ramp from -1.75 V to -0.9 V . The initial voltage traveling down the line is:

$$
V_{S}=(50 / 56)^{*} 0.85=0.76 \mathrm{~V}
$$

From Equations 7 and 8:

$$
\rho_{\mathrm{L}}=\left(\mathrm{R}_{\mathrm{T}}-\mathrm{Z}_{0}\right) /\left(\mathrm{R}_{\mathrm{T}}+\mathrm{Z}_{0}\right)=(65-50) /(65+50)=0.13
$$

$$
\rho_{S}=\left(R_{S}-Z_{0}\right) /\left(R_{S}+Z_{0}\right)=(6-50) /(6+50)=-0.79
$$

From Equation 9, the output voltage $\mathrm{V}_{\mathrm{T}}$ after one line delay is:

$$
\mathrm{V}_{\mathrm{T}}\left(\mathrm{~L}, \mathrm{~T}_{\mathrm{PD}}\right)=\mathrm{V}_{\mathrm{A}}(\mathrm{t})^{*}\left[1+\rho_{\mathrm{L}}\right]+\mathrm{V}_{\mathrm{DC}}=-0.71 \mathrm{~V}
$$

Likewise, after a time equal to three times the line delay, the output voltage $\mathrm{V}_{\mathrm{T}}$ is

$$
\begin{aligned}
& \mathrm{V}_{\mathrm{T}}\left(\mathrm{~L}, 3 \mathrm{~T}_{\mathrm{PD}}\right)=\mathrm{V}_{\mathrm{A}}(\mathrm{t})^{*}\left[\rho_{\mathrm{L}}{ }^{*} \rho_{\mathrm{S}}+\rho_{\mathrm{L}}{ }^{* *} 2^{*} \rho_{\mathrm{S}}\right]+\mathrm{V}_{\mathrm{T}}(\mathrm{~L}, \mathrm{TPD})= \\
& -0.83 \mathrm{~V}
\end{aligned}
$$

Additional iterations of Equation 9 can be performed to show that the ringing asymptotically approaches the final line voltage of -0.82 V . Ringing is a characteristic response for transmission lines mismatched at both ends with $R_{T}>R_{O}$. A SPICE representation of configuration 1 is illustrated in Figure 2.5.

Figure 2.5. SPICE Results for Circuit of Figure 2.4

## Configuration 2: $R_{T}<Z_{O}$

For the case in which $R_{T}<Z_{O}, \rho_{L}$ is negative, and the initial current at node "a" is less than the final quiescent current.

$$
\mathrm{I}_{\mathrm{INITIAL}}<\mathrm{I}_{\mathrm{F}}
$$

Hence:

$$
\left(\mathrm{V}_{\mathrm{S}} / \mathrm{Z}_{\mathrm{O}}\right)<\left(\mathrm{V}_{\mathrm{S}} / \mathrm{R}_{\mathrm{T}}\right)
$$

The reflected current, $\mathrm{I}_{\mathrm{R}}$, flows in the same direction as the initial source current in order to attain the final steady state current. The unique characteristic of configuration 2 is the negative reflection coefficient at both the source and load ends of the transmission line (Figure 2.6). Thus, signals approaching either end of the line are reflected with opposite polarity. In addition, the line voltage is a function of the pulse duration yielding steps of decreasing magnitude for input pulse durations greater than the line delay, and a series of attenuated pulses for input pulse durations less than the line delay.

Figure 2.6. Reflected Voltage Wave for $\mathbf{R}_{\mathbf{T}}<\mathrm{Z}_{\mathbf{O}}$

An example of a line mismatched at both ends, with the termination resistance less than the line resistance, and the input pulse width greater than the line delay is shown in Figure 2.7.

The initial steady state output voltage is defined as:

$$
\mathrm{V}_{\mathrm{TI}}=(35 / 41)^{*}(-1.75)=-1.49 \mathrm{~V}
$$

The final steady state output voltage is given by

Figure 2.7. Transmission Line Model for $\mathbf{R}_{\mathbf{T}}<\mathbf{Z}_{\mathbf{O}}$

$$
\mathrm{V}_{\mathrm{TF}}=(35 / 41)^{*}(-0.9)=-0.77 \mathrm{~V}
$$

For an input pulse from -1.75 V to -0.9 V the initial voltage traveling down the line is:

$$
V_{S}=(50 / 56)^{*} 0.85=0.76 \mathrm{~V}
$$

From Equations 7 and 8,

$$
\begin{aligned}
& \rho_{\mathrm{L}}=(35-50) /(35+50)=-0.18 \\
& \rho_{\mathrm{S}}=(6-50) /(6+50)=-0.79
\end{aligned}
$$

From Equation 9, the output voltage $\mathrm{V}_{\mathrm{T}}$ after one line delay is:

$$
\mathrm{V}_{\mathrm{T}}(\mathrm{~L}, \mathrm{~T} P \mathrm{P})=\mathrm{V}_{\mathrm{A}}(\mathrm{t})^{*}\left[1+\rho_{\mathrm{L}}\right]+\mathrm{V}_{\mathrm{DC}}=-0.87 \mathrm{~V}
$$

Likewise, after a time equal to three times the line delay, the output voltage $\mathrm{V}_{\mathrm{T}}$ is:

$$
\begin{aligned}
& \mathrm{V}_{\mathrm{T}}\left(\mathrm{~L}, 3 \mathrm{~T}_{\mathrm{PD}}\right)=\mathrm{V}_{\mathrm{A}}(\mathrm{t})^{*}\left[\rho_{\mathrm{L}}{ }^{*} \rho_{\mathrm{L}}+\rho_{\mathrm{L}}{ }^{* *} 2^{*} \rho_{\mathrm{S}}\right]+\mathrm{V}_{\mathrm{T}}(\mathrm{~L}, \mathrm{TPD})= \\
& -0.78 \mathrm{~V}
\end{aligned}
$$

Additional iterations of Equation 9 can be performed to show that the output response asymptotically approaches -0.77
volts. Stair-steps are characteristic responses for transmission lines mismatched at both ends with $\mathrm{R}_{\mathrm{T}}<\mathrm{Z}_{\mathrm{O}}$, and a pulse width greater than the line delay. Figure 2.8 shows the results of a SPICE simulation for the case described by configuration 2.

Figure 2.8. SPICE Results for Circuit of Figure 2.7 with Input Pulse Width > Line Delay
Figure 2.9 shows the line response for the same circuit as above, but for the case in which the input pulse width is less than the line delay. As in the previous example, the initial steady state voltage across the transmission line is -1.49 volts, and the reflection coefficients are -0.18 and -0.79 for the load and source respectively. However, the intermediate voltage across the transmission line is a series of positive-going pulses of decreasing amplitude for each round

Figure 2.9. SPICE Results for Circuit of Figure 2.7 with Input Pulse < Line Delay
trip of the reflected voltage, until the final steady state voltage of 1.49 volts is reached.

## Shorted Line

The shorted line is a special case of configuration 2 in which the load reflection coefficient is -1.0 , and the reflections tend toward the steady state condition of zero line voltage and a current defined by the source voltage and the source resistance.

Figure 2.10. Transmission Line Model for Shorted Line

An example of a shorted line is shown in Figure 2.10. The transmission line response for the case in which the input pulse width is greater than the line delay is shown in Figure 2.11. The initial and final steady state voltages across the transmission line are zero. The source is a step function with a 0.85 volt amplitude. The initial voltage traveling down the line is:

$$
\mathrm{V}_{\mathrm{S}}=(50 / 66.7)^{*} 0.85=0.64 \mathrm{~V}
$$

From Equations 7 and 8,
$\rho_{\mathrm{L}}=(0-50) /(0+50)=-1$

$$
\rho_{S}=(16.7-50) /(16.7+50)=-0.5
$$

Upon reaching the shorted end of the line, the initial voltage waveform is inverted and reflected toward the source. At the source end, the voltage is partially reflected back toward the shorted end in accordance with the source reflection coefficient. Thus, the voltage at the shorted end of the transmission line is always zero while at the source end, the voltage is reduced for each round trip of the reflected voltage. The voltage at the source end tends toward the final steady state condition of zero volts across the transmission line. The values of the source and line characteristic impedances in this example are such that the amplitude decreases by $50 \%$ with each successive round trip across the transmission line.

Figure 2.11. SPICE Results for Shorted Line with the Input Pulse Width > Line Delay

Figure 2.12 shows the line response for the same circuit as above, but for the case in which the input pulse width is less than the line delay. As in the previous example, the initial and final steady state voltages across the transmission line are zero, and the reflection coefficients are -1.0 and -0.5 for
the load and source respectively. However, the intermediate voltage across the transmission line is a series of negative pulses with the amplitude of each pulse decreasing for each round trip of the reflected voltage until the final steady state voltage of zero volts is attained. Again, for this example, the amplitude of the output response decreases by $50 \%$ for each successive reflection

Figure 2.12. SPICE Results for Shorted Line with the Input Pulse Width < Line Delay
due to the choice of source and transmission line characteristic impedances.

## Case 2: $\mathbf{R s} \leq \mathbf{Z O}_{\mathbf{O}} ; \mathbf{R T}_{\mathbf{T}}=\mathbf{Z O}_{\mathbf{O}}$

As in Case 1, the initial current in the transmission line is determined by the ratio of $V_{S} / Z_{O}$. Similarly, since $R_{T}=Z_{O}$ the final steady state current is also determined by the ratio $\mathrm{V}_{\mathrm{S}} / \mathrm{Z}_{\mathrm{O}}$. Because a discontinuity does not exist at the line-load interface, all the energy in the traveling step is absorbed by the termination resistance, in accordance with Ohm's Law. Therefore, no reflections occur and the output response is merely a delayed version of the input waveform.

Figure 2.13. Transmission Line Model for Matched Termination

An example of a line mismatched at the source but matched at the load is shown in Figure 2.13. For an input pulse of -1.75 V to -0.9 V is given by:

$$
\mathrm{V}_{\mathrm{T} I}=(50 / 56)^{*}(-1.75)=-1.56 \mathrm{~V}
$$

The final steady state output voltage is given by

$$
\mathrm{V}_{\mathrm{TF}}=(50 / 56)^{*}(-0.9)=-0.80 \mathrm{~V}
$$

The source is a step function with an 0.85 volt amplitude. The initial voltage traveling down the line is:

$$
V_{S}=(50 / 56)^{*} 0.85=0.76 \mathrm{~V}
$$

From Equations 7 and 8,

$$
\begin{aligned}
& \rho_{\mathrm{L}}=(50-50) /(65+50)=0 \\
& \rho_{\mathrm{S}}=(6-50) /(6+50)=-0.79
\end{aligned}
$$

From Equation 9, the output voltage $\mathrm{V}_{\mathrm{T}}$ after one line delay is:

$$
\mathrm{V}_{\mathrm{T}}\left(\mathrm{~L}, \mathrm{~T}_{\mathrm{PD}}\right)=\mathrm{V}_{\mathrm{A}}(\mathrm{t})^{*}\left[1+\rho_{\mathrm{L}}\right]+\mathrm{V}_{\mathrm{DC}}=-0.80 \mathrm{~V}
$$

Likewise, after a time equal to three times the line delay, the output voltage $\mathrm{V}_{\mathrm{T}}$ is:

$$
\begin{aligned}
& \mathrm{V}_{\mathrm{T}}\left(\mathrm{~L}, 3 \mathrm{~T}_{\mathrm{PD}}\right)= \\
& \mathrm{V}_{\mathrm{A}}(\mathrm{t})^{*}\left[\rho_{\mathrm{L}}{ }^{*} \rho_{\mathrm{S}}+\rho_{\mathrm{L}}{ }^{* *} 2^{*} \rho_{\mathrm{S}}\right]+\mathrm{V}_{\mathrm{T}}(\mathrm{~L}, \mathrm{TPD})=-0.80 \mathrm{~V}
\end{aligned}
$$

Thus, the output response attains its final steady state value (Figure 2.14) after only one line delay when the termination

Figure 2.14. SPICE Results for Matched Termination
resistance matches the line characteristic impedance. Ringing or stair-step output responses do not occur since the load reflection coefficient is zero.

## Case 3: $\mathbf{R}_{\mathbf{S}}=\mathbf{Z}_{\mathbf{O}} ; \mathbf{R}_{\mathbf{T}}=\mathbf{Z}_{\mathbf{O}}$

When the termination resistance does not match the line characteristic impedance reflections arising from the load will occur. Fortunately, in case 3, the source resistance and the line characteristic impedance are equal, thus, the reflection coefficient is zero and the energy in these reflections is completely absorbed at the source; thus, no further reflections occur.

Figure 2.15. Transmission Line Model for $\mathrm{V}_{\mathbf{S}}=\mathrm{Z}_{\mathbf{O}}$

An example of a line mismatched at the load but matched at the source is shown in Figure 2.15. For an input pulse of -1.75 V to -0.9 V the initial steady state output voltage is given by:

$$
\mathrm{V}_{\mathrm{T}}=(65 / 115)^{*}(-1.75)=-0.99 \mathrm{~V}
$$

The final steady state output voltage is given by

$$
\mathrm{V}_{\mathrm{TF}}=(65 / 115)^{\star}(-0.9)=-0.51 \mathrm{~V}
$$

The source is a step function with a 0.85 volt amplitude. The initial voltage traveling down the line is:

$$
\mathrm{V}_{\mathrm{S}}=(50 / 100)^{*} 0.85=0.43 \mathrm{~V}
$$

From Equations 7 and 8,

$$
\begin{aligned}
& \rho_{\mathrm{L}}=(65-50) /(65+50)=0.13 \\
& \rho_{\mathrm{S}}=(50-50) /(50+50)=0
\end{aligned}
$$

From Equation 9, the output voltage $\mathrm{V}_{\mathrm{T}}$ after one line delay is:

$$
\mathrm{V}_{\mathrm{T}}(\mathrm{~L}, \mathrm{~T} P \mathrm{P})=\mathrm{V}_{\mathrm{A}}(\mathrm{t})^{*}\left[1+\rho_{\mathrm{L}}\right]+\mathrm{V}_{\mathrm{DC}}=-0.51 \mathrm{~V}
$$

Likewise, after a time equal to three times the line delay, the output voltage $\mathrm{V}_{\mathrm{T}}$ is:

$$
\begin{aligned}
& \mathrm{V}_{\mathrm{T}}\left(\mathrm{~L}, 3 \mathrm{~T}_{\mathrm{PD}}\right)=\mathrm{V}_{\mathrm{A}}(\mathrm{t})^{*}\left[\rho_{\mathrm{L}}{ }^{*} \rho_{\mathrm{S}}+\rho_{\mathrm{L}}{ }^{* *} 2^{*} \rho_{\mathrm{S}}\right]+\mathrm{V}_{\mathrm{T}}(\mathrm{~L}, \mathrm{~T} P \mathrm{P})= \\
& -0.51 \mathrm{~V}
\end{aligned}
$$

Thus, the output response attains its final steady state value after one line delay when the source resistance matches the line characteristic impedance. Again, ringing or a stair-step output does not occur since the load reflection coefficient is zero (Figure 2.16).

5

Figure 2.16. SPICE Results for Circuit of Figure 2.15

## Series Termination

Series termination represents a special subcategory of Case 3 in which the load reflection coefficient is +1 and the source resistance is made equal to the line characteristic impedance by inserting a resistor, $\mathrm{R}_{\mathrm{ST}}$, between and in series with, the transmission line and the source resistance $\mathrm{R}_{\mathrm{O}}$. The
reflections tend toward the steady state conditions of zero current in the transmission line, and an output voltage equal to the input voltage. This type of termination is illustrated by the circuit configuration of Figure 2.17. The initial voltage down the line will be only half the amplitude of the input signal due to the voltage division of the equal source and line impedances.

$$
V_{S}=\left(Z_{O} /\left(2^{*} Z_{O}\right)\right)^{*} V_{I N}=V_{I N} / 2
$$

(Equation 10)
The load reflection coefficient tends to unity, thus, a voltage wave arriving at the load will double in amplitude, and a reflected wave with the same amplitude as the incident wave

Figure 2.17. Series Terminated Transmission Line
will be reflected toward the source. Since the source resistance matches the line characteristic impedance all the energy in the reflected wave is absorbed, and no further reflections occur. This "source absorption" feature reduces the effects of ringing, making series terminations particularly useful for transmitting signals through a backplane or other interconnects where discontinuities exist.

As stated previously, the signal in the line is only at half amplitude and the reflection restores the signal to the full amplitude. It is important to ensure that all loads are located near the end of the transmission line so that a two step input signal is not seen by any of the loads.

For the series terminated circuit of Figure 2.17 with $\mathrm{R}_{\mathrm{O}}+$ $\mathrm{R}_{\mathrm{ST}}=\mathrm{Z}_{\mathrm{O}}$ and an input pulse rising from -1.75 V to -0.9 V , the initial line voltage, $\mathrm{V}_{\mathrm{T}}$ is -1.325 V and the final line voltage, $\mathrm{V}_{\mathrm{TF}}$, is -0.9 V . The source is a step function with a 0.85 volt amplitude. The initial voltage traveling down the line is:
$\mathrm{V}_{\mathrm{S}}=(50 / 100)^{*} 0.85=0.43 \mathrm{~V}$
From Equations 7 and 8,
$\rho_{\mathrm{L}}=(\infty-50) /(\infty+50)=1$
$\rho_{S}=(50-50) /(50+50)=0$

From Equation 9, the output voltage $\mathrm{V}_{\boldsymbol{\top}}$ after one line delay is:
$\mathrm{V}_{\mathrm{T}}(\mathrm{L}, \mathrm{T} P \mathrm{D})=\mathrm{V}_{\mathrm{A}}(\mathrm{t})^{*}\left[1+\rho_{\mathrm{L}}\right]+\mathrm{V}_{\mathrm{DC}}=-0.9 \mathrm{~V}$
Likewise, after a time equal to three times the line delay, the output voltage $\mathrm{V}_{\top}$ is:
$\mathrm{V}_{\mathrm{T}}\left(\mathrm{L}, 3 \mathrm{~S}_{\mathrm{P}}\right)=\mathrm{V}_{\mathrm{A}}(\mathrm{t})^{*} \rho_{\mathrm{L}}{ }^{*} \rho_{\mathrm{S}}+\rho_{\mathrm{L}}{ }^{* *} \mathrm{Z}^{*} \rho_{\mathrm{S}}+\mathrm{V}_{\mathrm{T}}(\mathrm{L}, \mathrm{T} P \mathrm{D})=$ $-0.9 \mathrm{~V}$

Since the load reflection coefficient is unity, the voltage at the output attains the full ECL swing, whereas the voltage at the beginning of the transmission line does not attain this level until the reflected voltage arrives back at the source termination (Figures 2.17 and 2.18). No other reflections occur because the source impedance and line characteristic impedance match.

## Capacitive Effects on Propagation Delay

## Lumped Capacitive Loads

The effect of load capacitance on propagation delay must

Figure 2.18. SPICE Results for Series Terminated Line
be considered when using high performance integrated circuits such as the ECLinPS family. Although capacitive loading affects both series and parallel termination schemes, it is more pronounced for the series terminated case. Figure 2.19a illustrates a series terminated line with a capacitive load $C_{L}$. Under the no load condition, $C_{L}=0$, the delay between the $50 \%$ point of the input waveform to the $50 \%$ point of the output waveform is defined as the line delay $T_{D}$. A capacitive load

Figure 2.19a. Lumped Load Transmission Line Model
placed at the end of the line increases the rise time of the output signal, thereby increasing TD by an amount $\Delta \mathrm{T}_{\mathrm{D}}$ (Figure 2.19b). Figure 2.20 shows the increase in delay for load capacitances of $0,1,5,10$ and 20 picoFarads.

Figure 2.19b. $\Delta$ TD Introduced by Capacitive Load

Figure 2.20. Line Delay vs Lumped Capacitive Load
The increase in propagation delay can be determined by using Thevenin's theorem to convert the transmission line into a single time constant network with a ramp input voltage. The analysis applies to both series and parallel terminations, since both configurations can be represented as a single time constant network with a time constant, $\tau$, and a Thevenin impedance $Z$ '.

Figure 2.21 shows the Thevenized versions for the series and parallel terminated configurations. The Thevenin impedance for the series configuration is approximately twice that for the parallel terminated case, thus the time constant will be two times greater for the series terminated configuration. Since $\tau$ is proportional to the risetime, the rise time will also be two times greater; thus the reason for the larger impact of capacitive loading on the series terminated configuration.

THEVENIN EQUIVALENT SERIES TERMINATION

THEVENIN EQUIVALENT PARALLEL TERMINATION

Figure 2.21. Thevenin Equivalent Lumped Capacitance Circuits

Figure 2.22. Normalized Delay Increase Due to Lumped Capacitive Load

The relationship between the change in delay and the line-load time constant is shown in Figure 2.22. Both the delay change ( $\Delta T_{D}$ ) and the line-load time constant ( $Z^{\prime} C$ ) are normalized to the $20-80 \%$ risetime of the input signal. This chart provides a convenient graphical approach for approximating delay increases due to capacitive loads as illustrated by the following example.

## Transmission Line Theory

Given a $100 \Omega$ series terminated line with a 5 pF load at the end of the line and a no load rise time of 400ps, the increase in delay, $\Delta T_{\mathrm{D}}$, can be determined using Figure 2.22. The normalized line-load time constant is:

$$
Z \mathrm{C} / \mathrm{t} \mathrm{R}=100 \Omega^{*} 5 \mathrm{pF} / 400 \mathrm{ps}=1.25
$$

Using this value and Figure 2.22:

$$
\Delta \mathrm{T}_{\mathrm{D}} / \mathrm{tR}=0.9
$$

Therefore:

$$
\Delta T_{D}=0.9^{*} 400 \mathrm{ps}=360 \mathrm{ps}
$$

Thus, 360ps is added to the no load delay to arrive at the approximate delay for a $5 p F$ load. For a $100 \Omega$ line employing a matched parallel termination scheme, $Z^{\prime}=50 \Omega$, the added delay is only 240 ps. This added delay is significantly less than the one encountered for the series terminated case.

Thus, when critical delay paths are being designed it is incumbent on the designer to give special consideration to the termination scheme, lumped loading capacitance and line impedance to optimize the delay performance of the system.

## Distributed Capacitive Loads

In addition to lumped loading, capacitive loads may be distributed along transmission lines. There are three consequences of distributed capacitive loading of transmission lines: reflections, lower line impedance, and increased propagation delay. A circuit configuration for observing distributed capacitive loading effects is shown in Figure 2.23.

Figure 2.23. Transmission Line Model for Distributed Capacitive Load

Each capacitive load connected along a transmission line causes a reflection of opposite polarity to the incident wave. If the loads are spaced such that the risetime is greater than the time necessary for the incident wave to travel from one load to the next, the reflected waves from two adjacent loads will overlap. Figure 2.24 shows the output response for a transmission line with two distributed capacitive loads of 2.0 pF separated by a line propagation time of 750 ps . The upper trace, with a 20-80\% input signal risetime of 400ps, shows two distinct reflections. The middle and lower traces with $20-80 \%$ risetimes of 750 ps and 950 ps , respectively, show that overlap occurs as the risetime becomes longer than the line propagation delay.

Figure 2.24. Reflections Due to Distributed Capacitance

Increasing the number of distributed capacitive loads effectively decreases the line characteristic impedance as demonstrated by Figure 2.25. The upper trace shows that reflections occur for approximately 3.5 ns , during which time the characteristic impedance of the line appears lower( $\approx 76 \Omega$ ) than actual due to capacitive loading. After the reflections have ended, the transmission line appears as a short and the final steady state voltage is reached. The middle trace shows that decreasing the termination resistance to match the effective line characteristic impedance produces a response typical of a properly terminated line. Finally, the lower trace shows that the original steady state output can be attained by changing the source resistance to match the load resistance and the effective characteristic capacitance.

Figure 2.25. Characteristic Impedance Changes Due to Distributed Capacitive Loads

## Reduced Line Characteristic Impedance

To a first order approximation the load capacitance $\left(\mathrm{CL}_{\mathrm{L}}\right)$ is represented as an increase in the intrinsic line capacitance along that portion of the transmission line for which the load capacitances are distributed. If the length over which the load capacitances are distributed is defined as "L" the distributed value of the load capacitance ( $C_{D}$ ) is given by

$$
C D=C L / L
$$

(Equation 11)

The reduced line impedance is obtained by adding $\mathrm{C}_{\mathrm{D}}$ to $\mathrm{C}_{\mathrm{O}}$ in Equation 1.

$$
\mathrm{Z}_{\mathrm{O}} \sqrt{ }\left(\mathrm{~L}_{\mathrm{O}} / \mathrm{C}_{\mathrm{O}}\right)
$$

$$
\mathrm{Z}_{\mathrm{O}}{ }^{\prime} \sqrt{ }\left(\mathrm{L}_{\mathrm{O}} /\left(\mathrm{C}_{\mathrm{O}}+\mathrm{C}_{\mathrm{D}}\right)\right)=\sqrt{ }\left(\mathrm{L}_{\mathrm{O}} /\left(\mathrm{C}_{\mathrm{O}}{ }^{*}\left(1+\mathrm{C}_{\mathrm{D}} / \mathrm{C}_{\mathrm{O}}\right)\right)\right)
$$

$$
\begin{equation*}
Z_{O^{\prime}}^{\prime}=Z_{O} / \sqrt{ }\left(1+C_{D} / C_{O}\right) \tag{Equation12}
\end{equation*}
$$

For the circuit used to obtain the traces in Figure 2.25, the distributed load capacitance is 4 pF . From Equation 3, $\mathrm{C}_{\mathrm{O}}$ is calculated as

$$
\mathrm{Co}=750 \mathrm{ps} / 93 \Omega=8 \mathrm{pF}
$$

Hence:

$$
Z_{O^{\prime}} 93 \Omega / \sqrt{ }(1+4 p F / 8 p F)=76 \Omega
$$

Thus, the effective line impedance is $17 \Omega$ lower than the actual impedance while reflections are occurring on the line.

## Line Delay Increase

The increase in line delay caused by distributed loading is calculated by adding the distributed capacitance ( $C_{D}$ ) to the intrinsic line capacitance in Equation 2.

$$
\begin{aligned}
& \mathrm{TPD}=\sqrt{ }\left(\mathrm{L}_{\mathrm{O}}{ }^{*} \mathrm{C}_{\mathrm{O}}\right) \\
& \mathrm{TPD}^{\prime}=\sqrt{ }\left(\mathrm{L}_{O^{*}}\left(\mathrm{C}_{\mathrm{O}}+\mathrm{C}_{\mathrm{D}}\right)\right) \\
& \text { TPD' }=\mathrm{TPD}^{*} \sqrt{ }\left(1+\mathrm{CD}_{\mathrm{D}} / \mathrm{CO}_{\mathrm{O}}\right)
\end{aligned}
$$

(Equation 13 )
Once again, for the circuit used to obtain the traces in Figure 2.25, the distributed load capacitance is 4 pF . From the previous example, the intrinsic line capacitance is 8 pF therefore,

$$
\mathrm{TPD}^{\prime}=750 \mathrm{ps} * \sqrt{ }(1+4 \mathrm{pF} / 8 \mathrm{pF})=919 \mathrm{ps}
$$

Thus, the effect of distributed load capacitance on line delay is to increase the delay by 169ps. From Equation 13 it is obvious that the larger the $\mathrm{C}_{\mathrm{O}}$ of the line the smaller will be the increase in delay due to a distributive capacitive load. Therefore, to obtain the minimum impedance change and lowest propagation delay as a function of gate loading, the lowest characteristic impedance line should be used as this results in a line with the largest intrinsic line capacitance.

# SECTION 3 System Interconnect 

## Introduction

As mentioned earlier, edge rates of the ECLinPS family are such that most interconnects must be treated as transmission lines. Thus, a controlled impedance environment is necessary to produce predictable interconnect delays as well as limiting the reflection phenomena of undershoot and overshoot. The three most common techniques for circuit and/or system interconnect at high data rates are microstrip, stripline and coaxial cable; both microstrip and stripline are printed circuit board methods, whereas coaxial cable is most often used for interconnecting different parts of a system which are separated by relatively large distances. For slower speed applications ( $<300 \mathrm{MHz}$ ), a twisted pair scheme also works well. The scope of this writing will not include the twisted pair technique; however, a detailed discussion of this topic can be found in the MECL System Design Handbook. Finally, wirewrap boards are not recommended for the ECLinPS family because the fast edge speeds exceed the capabilities of normal wirewrapped connections. Mismatches at the connections cause reflections which distort the fast signal, significantly reducing the noise immunity of the system and perhaps causing erroneous operation.

## Printed Circuit Boards

Printed circuit boards (PCB's) provide a reliable and economical means of interconnecting electrical signals between system components. Printed circuit boards consist of a dielectric substrate over which the conducting printed circuit material is placed. Three major categories of printed circuit boards exist:

1. Single-sided boards
2. Double-sided boards
3. Multilayer boards

The most common printed circuit board material used for digital designs is a glass-epoxy laminate. These boards use a fiberglass dielectric with copper foils bonded to both sides of the dielectric material by an epoxy resin. Other substrate materials include a fiberglass dielectric with a polyimide resin and fiberglass dielectric with a teflon resin. For multilayer boards, the inner layers are separated by sheets of prepreg which acts as both a dielectric material and a bonding agent between layers.

The choice of substrate material depends on the function for which the board will be used, the environment in which the board is to operate, and costs. Table 3.1 lists several physical qualities which characterize several of the the available PCB types. Each available substrate material has its own properties which makes it ideally suited for particular applications.

## Glass-Epoxy

Possesses good moisture absorption, chemical and heat resistance properties as well as mechanical strength over standard humidity and temperature ranges. The most widely used versions are G10 and FR4, the fire resistant version of G10.

## Glass-Polyimide

Good for elevated temperature operation because of its tight tolerance of the coefficient of thermal expansion. Very hard material, so it may damage drilling equipment when being drilled.

## Glass-Teflon

Good for use when a low dielectric material is required. Very soft material, so it may be difficult to build features requiring precise geometries. Relatively expensive material.

| Material | Dielectric <br> Constant | Dissipation <br> Factor | Thermal Coefficient <br> of Expansion | Tensile <br> Modulus |
| :---: | :---: | :---: | :---: | :---: |
| Glass-Epoxy | $4.8(1.0 \mathrm{MHz})$ | $0.022(1.0 \mathrm{MHz})$ | $13-16\left(10^{-6}{ }^{\circ} \mathrm{C}\right)$ | 2.5 |
| PTFE | $2.1(10 \mathrm{GHz})$ | $0.0004(10 \mathrm{GHz})$ | $224\left(10^{-6}{ }^{\circ} \mathrm{C}\right)$ | 0.05 |
| Glass-Polyimide | $4.5(1.0 \mathrm{MHz})$ | $0.10(1.0 \mathrm{MHz})$ | $12-14\left(10^{-6}{ }^{\circ} \mathrm{C}\right)$ | 2.8 |

Table 3.1. Characteristics of Common PCB Materials

## Microstrip

A microstrip line is the easiest printed circuit interconnect to fabricate because it consists simply of a ground plane and flat signal conductor separated by a dielectric (Figure 3.1).

Figure 3.1. Microstrip Line

The characteristic impedance, $\mathrm{Z}_{\mathrm{O}}$, of a microstrip line is given by:
$Z_{O}=\frac{87}{\sqrt{ }\left(\varepsilon_{r}+1.41\right)} \ln \left[\frac{\left(5.98{ }^{*} h\right)}{(0.8 w+t)}\right]$
(Equation 1)
where:

$$
\begin{array}{lr}
\varepsilon_{r} & =\text { Relative Dielectric Constant of the Substrate } \\
\mathrm{w} & =\text { Width of the Signal Trace } \\
\mathrm{t} & =\text { Thickness of Signal Trace } \\
\mathrm{h} & =\text { Thickness of the Dielectric }
\end{array}
$$

Equation 1 is accurate to within $\pm 5 \%$ when:

$$
0.1<w / h<3.0 \text { and } 1<\varepsilon_{r}<15
$$

To mitigate the effects of electric field fringing, an additional constraint is that the width of the ground plane be such that it extends past each edge of the signal line by at least the width of the signal line.

Figure 3.2. Microstrip Impedance vs Trace Width

Figure 3.3. Line Capacitance vs Line Impedance and Trace Width

Figure 3.2 is a plot of characteristic impedance as a function of trace width and dielectric thickness for a dielectric constant of 4.8 and a trace thickness of 1.4 mils (1 ounce copper). Using the equation for $\mathrm{C}_{\mathrm{O}}$, developed in the previous chapter, and Equation 1, above, the capacitance per unit length can be calculated for various trace widths. Figure 3.3 Plots $\mathrm{C}_{\mathrm{O}}$ vs trace width for several different dielectric thicknesses. In addition, Figure 3.3 plots $\mathrm{Co}_{\mathrm{o}}$ vs the characteristic impedance for a microstrip line for the dielectric constant and trace thickness given above. The propagation delay for a signal on a microstrip line is described by the following equation:

$$
\begin{equation*}
\text { TPD }=1.016 \sqrt{ }\left(0.475^{*} \varepsilon_{r}+0.67\right) \text { ns/foot } \tag{eqt2}
\end{equation*}
$$

where:
$\varepsilon_{r} \quad=$ Dielectric Constant of the Board Material

Note that the propagation delay is dependent only on the dielectric constant of the PCB substrate. Figure 3.4 plots the propagation delay of a microstrip line versus the dielectric constant of the PCB.

Figure 3.4. Propagation Delay vs Dielectric Constant

## Stripline

Stripline is a printed circuit board interconnect in which a signal conductor is placed in a dielectric medium which is "sandwiched" between two conducting layers (Figure 3.5).

Figure 3.5. Stripline Structure
The characteristic impedance of the stripline is given by:

$$
\mathrm{Z}_{\mathrm{O}}=\frac{60}{\sqrt{ } \varepsilon_{r}} \ln \left[\frac{4 \mathrm{~b}}{0.67 \pi(0.8 w+t)}\right]
$$

(Equation 3)
5
where:

| $\varepsilon_{r}$ | $=$ Relative Dielectric Constant of the Substrate |
| :--- | ---: |
| $w$ | $=$ Width of the Stripline |
| $t$ | $=$ Thickness of the Stripline |
| $b$ | $=$ Distance Between the Two Ground Planes |

Equation 3 is accurate for the following dimension ratios:
$\mathrm{w} /(\mathrm{b}-\mathrm{t})<0.35$ and $\mathrm{t} / \mathrm{b}<0.25$

Once again, using a fairly typical $\varepsilon_{r}$ of 4.8 and a copper trace thickness of 1.4 mils, the characteristic impedance of a stripline interconnect can be plotted for various trace widths and dielectric thicknesses (Figure 3.6).

As was the case with a microstrip line, the capacitance per unit length of a stripline trace can be calculated using the $\mathrm{CO}_{\mathrm{O}}$ equation from Chapter 2. The graphs of Figure 3.7 plot the

Figure 3.6. Stripline Impedance vs Trace Width

Figure 3.7. Stripline Capacitance vs Impedance and Trace Width
capacitance of a stripline structure for a number of trace widths as well as the Co versus the characteristic impedance of the line.

The propagation delay of a stripline trace is governed by the simple equation:

$$
\mathrm{TPD}=1.016 \sqrt{ } \varepsilon_{r} \mathrm{~ns} / \mathrm{ft}
$$

(Equation 4)
where:
$\varepsilon_{r} \quad=$ Dielectric Constant of the Board Material

Again, the propagation delay of the trace is dependent only on the relative dielectric constant of the PCB substrate. Using Equation 4 the delay of the line can be plotted vs dielectric constant ( Figure 3.8 ).

Figure 3.8. Stripline Propagation Delay vs Dielectric Constant

## General Information

Since fiberglass-epoxy is by far the most widely used substrate in the industry, two important considerations should be mentioned:

1. The propagation delay for microstrip is $\approx 145$ ps per inch, whereas that for stripline is $\approx 185$ ps per inch. Since the propagation delay is governed by the dielectric of the substrate, a board material with a lower dielectric constant than glass-epoxy is required if a lower propagation delay is desired.
2. Cross coupled noise due to board geometries may require a substrate material with a lower dielectric constant. For example, the distance from the signal trace to the ground plane is a function of the substrate dielectric constant for a specified line characteristic impedance. Hence, the switching energy coupled into adjacent traces on the same signal plane is also a function of the dielectric constant. If the dielectric thickness and trace width must be maintained for a given line impedance, the spacing between traces must be increased to maintain the noise margin. Since the dielectric constant of glass-epoxy is relatively large, the increase in spacing between the traces may be unacceptable. So, a substrate material with a lower dielectric constant may be desirable. Generally, if the distance between traces is maintained at twice the distance to the ground plane, coupling between traces will be minimal.

Finally, printed circuit signal line shape variations play a significant role in modulating both the capacitance and
inductance per unit length for a transmission line; in other words, shape variations cause reflections. Bends in printed circuit traces cause an increase in the capacitance per unit length and a decrease in the inductance per unit length with a pronounced effect for angles of $90^{\circ}$ or more. Two techniques available to compensate for shape changes are:

1. Maintain a uniform trace width.
2. Cut the corners of the trace such that the length of the diagonal cut is in the range of 1.6 to 2.0 times the trace width.

Figure 3.9 illustrates these two techniques.

Figure 3.9. Compensation for Capacitive Effects of Trace Angles

## Coaxial Cable

Coaxial cable is a two conductor transmission line consisting of a concentric inner conductor surrounded by a dielectric which in turn is surrounded by a tubular outer conductor (Figure 3.10). It is ideal for transmitting high frequency signals over long distances because of its well defined and uniform characteristic impedance. Moreover, crosstalk is minimized by the ground shield provided by the outer conductor.

The propagation delay is derived in the same way as a stripline interconnect and, thus, is described by Equation 4. Therefore, as with stripline structures, the delay is a function

Figure 3.10. Cross Section of Coaxial Cable
of only the dielectric constant. The characteristic impedance and capacitance per unit length are parameters specified by the coaxial cable manufacturer; hence, the designer should look to the cable manufacturer for these parameters.

## Coaxial Cable Lengths

The ECLinPS family operates with rise times as fast as several hundred picoseconds; thus, coaxial cable must be able to transmit these pulses without introducing a significant distortion. Viewing the ECLinPS output as a single time constant driver circuit terminated with a $50 \Omega$ load, the required line bandwidth $\left(\mathrm{f}_{\mathrm{c}}\right)$ can be calculated as follows.

$$
\mathrm{f}_{\mathrm{C}}=0.35 / \mathrm{tR} \quad \text { (Equation 5) }
$$

where:

$$
\text { tR } \quad=10 \% \text { to } 90 \% \text { Rise Time }
$$

Converting the typical $20 \%-80 \%$ rise time value of 400 ps to an equivalent $10 \%-90 \%$ rise time value of 530 ps , and using Equation 5 yields a bandwidth value of $\mathrm{f}_{\mathrm{C}}=660 \mathrm{MHz}$

Below 1.0 GHz the primary loss mechanism in transmission lines is skin effect, as dielectric losses for materials such as polyethylene and teflon are insignificant below this value. Since attenuation due to skin effect is proportional to the square root of frequency, a log-log plot of attenuation versus frequency produces a linear result. The maximum coaxial cable lengths for the ECLinPS family can be derived from the plot in Figure 3.11.

Figure 3.11. Coaxial Cable Attenuation vs Frequency

Typically for an ECL system, the minimum peak-to-peak signal swing is 600 mV . The nominal peak-to-peak signal swing for the ECLinPS family is approximately 850 mV . Thus, the maximum permissible attenuation is:

$$
\begin{aligned}
\operatorname{Loss}(\mathrm{dB}) & =20^{*} \log \left(\mathrm{~V}_{\mathrm{IN}} / \mathrm{V}_{\mathrm{O}}\right) \\
& =20^{*} \log (0.85 / 0.6)=3.0 \mathrm{~dB} .
\end{aligned}
$$

From Figure 3.11 the loss at 660 MHz for RG58/U cable is 15 $\mathrm{dB} / 100$ feet. Therefore, the maximum length is

Additional information concerning coaxial cable can be found in Motorola's MECL System Design Handbook.

## Summary of Values

Table 3.2 is a compilation of propagation delays at nominal dielectric values for the three types of interconnects discussed.

| Interconnect | TPD | $\varepsilon_{\boldsymbol{r}}$ |
| :---: | :---: | :---: |
| Microstrip | $145 \mathrm{ps} / \mathrm{in}$ | 4.8 |
| Stripline | $185 \mathrm{ps} / \mathrm{in}$ | 4.8 |
| Coaxial Cable | $123 \mathrm{ps} / \mathrm{in}$ | 2.1 |

Table 3.2-Comparison of Interconnect Medium

## Termination Techniques

From transmission line theory, a signal propagating down the line is partially reflected back to the source if the line is not terminated in its characteristic impedance. The magnitude of the reflected voltage signal is governed by the load reflection coefficient, $\rho_{\mathrm{L}}$.

$$
\begin{equation*}
\rho_{\mathrm{L}}=\left(\mathrm{R}_{\mathrm{T}}-\mathrm{Z}_{\mathrm{O}}\right) /\left(\mathrm{R}_{\mathrm{T}}+\mathrm{Z}_{0}\right) \tag{Equation6}
\end{equation*}
$$

where:
RT
= Load Impedance, and
ZO $\quad=$ Characteristic Impedance of the Line

When the reflected signal arrives at the source it is re-reflected back toward the load with a magnitude dictated by the source reflection coefficient, $\rho_{\mathrm{S}}$.

$$
\begin{equation*}
\rho_{S}=\left(R_{S}-Z_{O}\right) /\left(R_{S}+Z_{O}\right) \tag{Equation7}
\end{equation*}
$$

where:

| RS | $=$ Source Impedance |
| :--- | :--- |
| $Z_{O}$ | $=$ Characteristic Impedance of the Line |

The reflected signal continues to be re-reflected by the source and load impedances and is attenuated with each passage over the transmission line. The output response appears as a damped oscillation asymptotically approaching the steady state value. This phenomena is often referred to as ringing.

The importance of minimizing the reflected signals lies in their adverse affect on noise margin and the potential for driving the input transistors of the succeeding stage into saturation. Both of these phenomena can lead to less than ideal system performance. To minimize the potential hazards associated with reflections on transmission lines three basic termination techniques are available:

1. Minimizing Unterminated line lengths
2. Parallel Termination
3. Series Termination

## Unterminated Lines

Figure 3.12 illustrates an unterminated transmission line. This configuration is also referred to as a stub or an open line.

Figure 3.12. Unterminated Transmission Line
The function of $R_{E}$ is to provide the drive current for a high to low transition at the driver output. Since the reflection coefficient at the load is of opposite polarity to that at the source, the signal will be reflected back and forth over the transmission with the polarity changing after each reflection from the source impedance. Thus, steps appear at the input to the receiving gate. When $R_{E}$ is too large, steps appear in the trailing edge of the propagating signal that slows the edge speed of the input to the receiving gate, subsequently causing an increase in the net propagation delay. A reasonable negative-going signal swing at the input of the receiving gate results when the value of $R_{E}$ is selected to produce an initial step of 600 mV at the driving gate. Hence:

$$
\begin{aligned}
& I^{*} \mathrm{Z}_{\mathrm{O}}>0.6 \\
& \left(\mathrm{~V}_{\mathrm{OH}}-\mathrm{V}_{\mathrm{EE}}\right) /\left(\mathrm{R}_{\mathrm{E}}+\mathrm{Z}_{\mathrm{O}}\right)^{*} \mathrm{Z}_{\mathrm{O}} \geq 0.6 \\
& 6.2 \mathrm{Z}_{\mathrm{O}} \geq \mathrm{R}_{\mathrm{E}}(10 \mathrm{E}), 4.9 \mathrm{Z}_{\mathrm{O}} \geq \mathrm{R}_{\mathrm{E}}(100 \mathrm{E}) \\
& \text { (Equation 9) }
\end{aligned}
$$

Load resistors of less than $180 \Omega$ should not be used because the heavy load may cause a reduction in noise immunity when the output is in the high state due to an increased output emitter-follower $\mathrm{V}_{\mathrm{BE}}$ drop.

When the driver gate delivers a full ECL swing, the signal propagates from point $A$ arriving at point $B$ a time $T_{D}$ later. At point $B$, the signal is reflected as a function of $\rho_{L}$. The input impedance of the receiving gate is large relative to the line characteristic impedance, therefore:

$$
\begin{equation*}
\rho_{\mathrm{L}}=\left(\mathrm{R}_{\mathrm{T}}-\mathrm{Z}_{\mathrm{O}}\right) /\left(\mathrm{R}_{\mathrm{T}}+\mathrm{Z}_{\mathrm{O}}\right) \approx 1 \tag{Equation10}
\end{equation*}
$$

A large positive reflection occurs resulting in overshoot. The reflected signal reaches point $A$ at time $2 \mathrm{~T}_{\mathrm{D}}$, and a large negative reflection results because the output impedance of the driver gate is much less than the line characteristic impedance (i.e. $\mathrm{R}_{\mathrm{O}} \ll \mathrm{Z}_{\mathrm{O}}$ ). In this case, the reflection coefficient is negative.

$$
\begin{equation*}
\rho \mathrm{S}=\left(\mathrm{R}_{\mathrm{O}}-\mathrm{Z}_{\mathrm{O}}\right) /\left(\mathrm{R}_{\mathrm{O}}+\mathrm{Z}_{\mathrm{O}}\right) \tag{Equation11}
\end{equation*}
$$

The signal is re-reflected back toward the load arriving at time $3 T_{D}$ resulting in undershoot at point $B$. This re-reflection of signals continues between the source and load impedances causing ringing to appear on the output response.

The impetus in restricting interconnect lengths is to mitigate the effects of overshoot and undershoot. A handy rule of thumb is that the undershoot can be limited to less than $15 \%$ of the logic swing if the two way line delay is less than the rise time of the pulse. With an undershoot of < $15 \%$, the physics of the situation will result in an overshoot which will not cause saturation problems at the receiving input. Thus, the maximum line length can be determined using Equation 12.

$$
\mathrm{L}_{\max }<\mathrm{t}_{\mathrm{R}} / 2^{*} \mathrm{~T}_{\mathrm{PD}} \text { (unit length) }
$$

(Equation 12)
where:
L
= Line Length

$$
\text { tR } \quad=\text { Rise time }
$$

TPD = Propagation Delay per unit Length
Further, the propagation delay increases with gate loading, thus, the actual delay per unit length (TPD') is given as:

$$
\text { TPD' }=\text { TPD }{ }^{*} \sqrt{ }\left(1+C D /\left(L^{*} C O\right)\right)
$$

Substitution of the modified delay per unit length into Equation 12 and rearranging yields Equation 13:

$$
\mathrm{t}_{\mathrm{R}} \geq\left(2^{*} \mathrm{~L}\right)^{*} \mathrm{TPD}^{*} \sqrt{ }\left(1+\mathrm{C}_{\mathrm{D}} /\left(\mathrm{L}^{*} \mathrm{C}_{\mathrm{O}}\right)\right) \text { (Equation 13) }
$$

Solving Equation 13 for the maximum line length produces:

$$
\begin{aligned}
L_{\max }=0.5^{*}\left(\sqrt { } \left(\left(\mathrm{C}_{\mathrm{D}} / \mathrm{C}_{\mathrm{O}}\right)^{* *} 2\right.\right. & (\text { (Equation 14) } \\
& +\left(\mathrm{t}_{\mathrm{R}} / \mathrm{TPD}_{\mathrm{PD}}\right)
\end{aligned}
$$

Assuming a worst case capacitance of 2 pF and a rise time of 200 ps for the ECLinPS family gives a value of 0.3 inches for the maximum open line length.

Table 3.3 shows maximum open line lengths derived from SPICE simulations for single and double gate loads, a maximum overshoot of $40 \%$ and undershoot of $20 \%$ was assumed. The simulation results indicate that for a $50 \Omega$ line, a stub length of $\leq 0.3$ inches will limit the overshoot to less than $40 \%$, and the undershoot to within $20 \%$ of the logic swing. Signal traces will most assuredly be larger than $0.3^{\prime \prime}$ for all but the simplest of interconnects, thus, for most practical applications, it will be necessary to use ECLinPS devices in a controlled impedance environment.

| $\mathbf{Z}_{\mathbf{O}(\Omega)}$ | Microstrip |  | Stripline |  |
| :---: | :---: | :---: | :---: | :---: |
|  | Fanout = 1 | Fanout = 2 | Fanout = 1 | Fanout = 2 |
|  | $\mathrm{L}_{\text {max }}$ (in) | $\mathrm{L}_{\text {max }}$ (in) | $\mathrm{L}_{\text {(max) }}$ (in) | $\mathrm{L}_{\text {(max) }}$ (in) |
| 50 | 0.3 | 0.2 | 0.3 | 0.15 |
| 68 | 0.3 | 0.15 | 0.25 | 0.1 |

## Parallel Termination

When the fastest circuit performance or the ability to drive distributed loads is desired, parallel termination is the method of choice. An important feature of the parallel termination scheme is the undistorted waveform along the full length of the line. A parallel terminated line is one in which the receiving end is terminated to a voltage ( $\mathrm{V}_{\mathrm{TT}}$ ) through a resistor ( $\mathrm{R} T$ ) with a value equal to the line characteristic impedance (Figure 3.13a). An advantage of this technique is that power consumption can be decreased by a judicious choice of $\mathrm{V}_{\mathrm{T} T}$. For $50 \Omega$ systems, the typical value of $\mathrm{V}_{\mathrm{TT}}$ is negative two volts.

FIGURE 3.13A PARALLEL TERMINATION TO V ${ }_{\text {TT }}$

FIGURE 3.13B THEVENIN EQUIVALENT PARALLEL TERMINATION

Although the single resistor termination to $\mathrm{V}_{\mathrm{TT}}$ conserves power, it offers the disadvantage of requiring an additional supply voltage. An alternate approach to using a single power supply is to use a resistor divider network as shown in Figure 3.13b. The Thevenin equivalent of the two resistors is a single resistor equal to the characteristic impedance of the line, and terminated to $\mathrm{V}_{\mathrm{TT}}$. The values for resistors R1 and R2 may be obtained from the following relationships:

$$
\begin{aligned}
& \mathrm{R}_{2}=\left(\mathrm{V}_{\mathrm{EE}} / \mathrm{V}_{\mathrm{TT}}\right)^{*} \mathrm{Z}_{\mathrm{O}} \\
& \mathrm{R}_{1}=\left(\mathrm{R}_{2}{ }^{*} \mathrm{~V}_{\mathrm{TT}}\right) /\left(\mathrm{V}_{\mathrm{EE}}-\mathrm{V}_{\mathrm{TT}}\right)
\end{aligned}
$$

(Equation 15)
(Equation 16)

For a nominal 10 E supply voltage of -5.2 V and $\mathrm{V}_{\mathrm{TT}}$ of -2 V :

$$
\begin{aligned}
& R_{2}=2.6^{*} Z_{O} \\
& R_{1}=R_{2} / 1.6
\end{aligned}
$$

(Equation 17)
(Equation 18)

For a nominal 100 E supply voltage of -4.5 V and $\mathrm{V}_{\mathrm{TT}}$ of -2 V

$$
\begin{aligned}
& \mathrm{R}_{2}=2.25{ }^{*} \mathrm{Z}_{\mathrm{O}} \\
& \mathrm{R} 1=\mathrm{R} 2 / 1.25
\end{aligned}
$$

(Equation 19)
(Equation 20)

Table 3.4 provides a reference of values for the resistor divider network of Figure 3.13b.

| ZO $(\Omega)$ | 10E |  | 100E |  |
| :---: | :---: | :---: | :---: | :---: |
|  | $\mathbf{R}_{\mathbf{1}}(\Omega)$ | $\mathbf{R}_{\mathbf{2}}(\Omega)$ | $\mathbf{R}_{\mathbf{1}}(\Omega)$ | $\mathbf{R}_{\mathbf{2}}(\Omega)$ |

| 150 | 243 | 390 | 270 | 338 |

Table 3.4. Thevenin Termination Resistor Values

For both configurations, when the equivalent termination resistance matches the line impedance no reflection occurs because all the energy in the signal is absorbed by the termination. Hence, the primary tradeoff between the two types of termination schemes are power versus power supply requirements. As mentioned earlier, the $\mathrm{V}_{\mathrm{T}}$ scenario requires an extra power supply; however, the Theveninization technique will consume 10 fold more DC power. Fortunately, this extra power consumption will not be seen on the die, therefore, both techniques will result in the same die junction temperatures.

ECLinPS output drivers consists of emitter followers designed to drive a $50 \Omega$ load into a negative two volt supply $\left(\mathrm{V}_{\mathrm{T} T}\right)$. Under these conditions, the nominal 10E output levels are -1.75 volts at 5 mA for the low state and -0.9 volts at 22 mA for the high state. For the 100E devices, the nominal output levels are -0.955 volts at 20.9 mA for the high state and 1.705 volts at 5.9 mA for the low state.

Figure 3.14 shows the nominal output characteristics for ECLinPS devices driving various load impedances returned to a negative two volt supply. This plot applies to both 10E and 100E versions of the ECLinPS family. The output resistances, $R_{H}$ (high state output resistance) and $R_{L}$ (low state output resistance), are obtained from the reciprocal of the slope at the desired operating point. Many applications require loads other than $50 \Omega$, the resulting $\mathrm{V}_{\mathrm{OH}}$ and $\mathrm{V}_{\mathrm{OL}}$ levels can be estimated using the following technique.

Figure 3.14. ECLINPS Output Characteristics

## 10E Devices

The equivalent output circuit is shown in Figure 3.15. The output levels are estimated from Figure 3.15 as follows:

$$
\mathrm{V}_{\mathrm{OH}}=-770 \mathrm{mV}-6^{*} \mathrm{I} \mathrm{HOUT}
$$

(Equation 21)

Figure 3.15. Equivalent Model for Calculating 10E Output Levels
where:

$$
\mathrm{I} \mathrm{HOUT}=\left(-770 \mathrm{mV}-\mathrm{V}_{\mathrm{TT}}\right) /\left(6 \Omega+\mathrm{R}_{\mathrm{T}}\right)
$$

and

$$
\text { VOL }=-1710 \mathrm{mV}-8^{*} 1 \mathrm{LOUT}
$$

(Equation 22)
where:

$$
\text { LLOUT }=\left(-1710 \mathrm{mV}-\mathrm{V}_{\mathrm{TT}}\right) /\left(8 \Omega+\mathrm{R}_{\mathrm{T}}\right)
$$

## 100E Devices

The equivalent output circuit is shown in Figure 3.16. The output levels are estimated from Figure 3.16 as follows:

$$
\mathrm{V}_{\mathrm{OH}}=-830 \mathrm{mV}-6^{*} \mathrm{I} \mathrm{HOUT}
$$

(Equation 23)
where:

Figure 3.16. Equivalent Circuit for Calculating 100E Output Levels
and

$$
\mathrm{V}_{0 \mathrm{~L}}=-1660 \mathrm{mV}-8^{*} \text { ILOUT }
$$

(Equation 24)
where:

$$
\text { ILOUT }=\left(-1660 \mathrm{mV}-\mathrm{V}_{\mathrm{TT}}\right) /\left(8 \Omega+\mathrm{R}_{\mathrm{T}}\right)
$$

## SIP Resistors

The choice of resistor type for use as the termination resistor has several alternatives. Although the use of a discrete, preferably chip resistor, offers the best isolation and lowest parasitic additions, there are SIP resistor packs which will work fine for ECLinPS designs. SIP resistors offer a level of density which is impossible to obtain using their discrete counterparts. However, there are some guidelines which the user should follow when using SIP resistor packs. Always terminate complimentary outputs in the same pack to minimize inductance effects on the SIP power pin. Noise generated on this pin will couple directly into all of the resistors in the pack. In addition, the SIP package should incorporate bypass capacitors in the design (Figure 3.17). These capacitors are necessary to help maintain a solid $\mathrm{V}_{\mathrm{T}}$ T level within the package, again mitigating any potential crosstalk or feed through effects. A 10 pin SIP like the DALE CSRC-10B21-500J/103M, is suitable for providing $50 \Omega$ terminations while maintaining a relatively noise free environment to non-switching inputs.

Figure 3.17. Standard ECL 10 pin SIP

## Series Termination Technique

Series Damping is a technique in which a termination resistance is placed between the driver and the transmission line with no termination resistance placed at the receiving end of the line (Figure 3.18).

Series Termination is a special case of series damping in which the sum of the termination resistor (RST) and the output impedance of the driving gate $\left(R_{O}\right)$ is equal to the line characteristic impedance.

Figure 3.18. Series Termination

As mentioned in the Transmission line section, series termination techniques are useful when the interconnect lengths are long or impedance discontinuities exist on the line. Additionally, the signal travels down the line at half amplitude minimizing problems associated with crosstalk. Unfortunately, a drawback with this technique is the possibility of a two step signal appearing when the driven inputs are far from the end of the transmission line. To avoid this problem, the distance between the end of the transmission line and input gates should adhere to the guidelines specified in Table 3.3 from the section on unterminated lines.

## Series Termination Theory

When the output of the series terminated driver gate switches, a change in voltage $\left(\Delta \mathrm{V}_{\mathrm{B}}\right)$ occurs at the input to the transmission line:

$$
\Delta \mathrm{V}_{\mathrm{B}}=\mathrm{V}_{I N} \text { * }\left(\mathrm{Z}_{\mathrm{O}}\right) /\left(\mathrm{R}_{\mathrm{ST}}+\mathrm{R}_{\mathrm{S}}+\mathrm{Z}_{\mathrm{O}}\right) \quad \text { (Equation 25) }
$$

where:
$\mathrm{V}_{\mathrm{IN}}=$ Internal Voltage Change
$\mathrm{Z}_{\mathrm{O}}=$ Line Characteristic Impedance
RS = Output Impedance of the Driver Gate
RST $=$ Termination Resistance
Since $Z_{O}=R_{S T}+R_{S}$ substitution into Equation 25 yields:

$$
\begin{equation*}
\Delta \mathrm{V}_{\mathrm{B}}=\mathrm{V}_{\mathrm{IN}} / 2 \tag{Equation26}
\end{equation*}
$$

From Equation 26 an incident wave of half amplitude propagates down the transmission line. Since the transmission line is unterminated at the receiving end, the reflection coefficient at the load is approximately unity; therefore, the reflection causes the voltage to double at the receiving end. When the reflected wave arrives at the source end, its energy is absorbed by the series resistance, producing no further reflections as the impedance is equal to the characteristic impedance of the line.

An extension of the series termination technique, using parallel fanout, eliminates the problem of lumped loading at the expense of extra transmission lines (Figure 3.19).

Figure 3.19. Parallel Fanout using Series Termination

## Calculation of $R_{E}$

$R_{E}$ functions to establish $\mathrm{V}_{\mathrm{OH}}$ and $\mathrm{V}_{\mathrm{OL}}$ levels and to provide the negative going drive into $\mathrm{R}_{S T}$ and $\mathrm{Z}_{O}$ when the driver output switches to the low state. The value of $R_{E}$ must
be such that the required current is supplied to each transmission line while not allowing the output transistor to turn off when switching from a high to a low state. An appropriate model is to treat the output emitter follower as a simple switch (Figure 3.20).

Figure 3.20. Equivalent Circuit for $\mathbf{R E}_{E}$ Determination

The worst case scenario occurs when the driver output emitter follower is cutoff during a negative going transition. When this happens, the switch can be considered opened and, at the instant it opens, the line characteristic impedance behaves as a linear resistor returned to $\mathrm{V}_{\mathrm{OH}}$. The model becomes a simple series resistive network as shown in Figure 3.21.

Figure 3.21. Equivalent Circuit with Output Cutoff

The maximum current occurs at the instant the switch opens and is given by Equation 27.

$$
I_{\mathrm{MAX}}=\left(\mathrm{V}_{\mathrm{OH}}-\mathrm{V}_{\mathrm{EE}}\right) /\left(\mathrm{R}_{\mathrm{E}}+\mathrm{R}_{\mathrm{ST}}=\mathrm{Z}_{\mathrm{O}}\right)(\text { Equation27 })
$$

The initial current must be sufficient to generate a transient voltage equal to half of the logic swing since the voltage at the receiving end of the line doubles for the series terminated case. To insure the pull down current is large enough to handle reflections caused by discontinuities and load capacitances, the transient voltage is increased by $25 \%$. Therefore,

$$
\begin{equation*}
\mathrm{I}_{\mathrm{INIT}}=\left(1.25^{*} \mathrm{~V}_{\mathrm{SWING}} / 2\right) / \mathrm{Z}_{\mathrm{O}} \tag{Equation28}
\end{equation*}
$$

To satisfy the initial constraints $I_{\text {MAX }}>I_{\text {INT }}$

$$
\left(\mathrm{V}_{\mathrm{OH}}-\mathrm{V}_{\mathrm{EE}}\right) /\left(\mathrm{R}_{\mathrm{E}}+\mathrm{R}_{\mathrm{ST}}+\mathrm{Z}_{\mathrm{O}}\right)>\left(1.25^{*} \mathrm{~V}_{\mathrm{SWI}} \mathrm{NG} / 2\right) / \mathrm{Z}_{\mathrm{O}}
$$

For the 10E series

$$
\begin{aligned}
& \mathrm{V}_{\mathrm{OH}}=-0.9 \mathrm{~V}, \mathrm{~V}_{\mathrm{SWING}}=0.85 \mathrm{~V}, \mathrm{~V}_{\mathrm{EE}}=-5.2 \\
& \left.[-0.9-(-5.2)] / \mathrm{R}_{\mathrm{ST}}+\mathrm{R}_{\mathrm{E}}+\mathrm{Z}_{\mathrm{O}}\right) \geq 0.531 / \mathrm{Z}_{\mathrm{O}}
\end{aligned}
$$

$$
7.10{ }^{*} \mathrm{Z}_{\mathrm{O}}-\mathrm{R}_{\mathrm{ST}} \geq \mathrm{R}_{\mathrm{E}}
$$

(Equation 29)

For the 100E series:

$$
\mathrm{V}_{\mathrm{OH}}=-0.955 \mathrm{~V}, \mathrm{~V}_{\text {SWING }}=0.75, \mathrm{~V}_{\mathrm{EE}}=-4.5 \mathrm{~V}
$$

$$
6.56^{*} \mathrm{Z}_{\mathrm{O}}-\mathrm{R}_{\mathrm{ST}}>\mathrm{R}_{\mathrm{E}}
$$

(Equation 30)
Figure 3.19 showed a modification of the series termination scheme in which several series terminated lines are driven by a single ECL gate. The principle concern when applying this technique is to maintain the current in the output emitter follower below the maximum rated value. The value for $R_{E}$ can be calculated by viewing the circuit in terms of conductances.

$$
\begin{equation*}
G_{E}>G_{1}+G_{2}+\ldots+G_{n} \tag{Equation31}
\end{equation*}
$$

For the 10E series

$$
\begin{array}{ll}
1 / R_{\mathrm{E}} \geq & 1 /\left(7.10^{*} \mathrm{Z}_{\mathrm{O} 1}-\mathrm{RST}_{\mathrm{S}}\right)+ \\
& 1 /\left(7.10^{*} \mathrm{Z}_{\mathrm{O} 2}-\mathrm{RST}_{2}\right)+ \\
& 1 /\left(7.10^{*} \mathrm{Z}_{03}-\mathrm{RSTn}_{\mathrm{S}}\right)
\end{array}
$$

For the case where

$$
\mathrm{Z}_{\mathrm{O} 1}=\mathrm{Z}_{\mathrm{O} 2}=\ldots \mathrm{Z}_{\mathrm{On}} \text { and } \mathrm{RST}_{\mathrm{S} 1}=\mathrm{RST}_{\mathrm{ST}}=\mathrm{RSTn}_{\mathrm{ST}}
$$

$$
R_{E} \leq\left(7.10{ }^{*} Z_{O}-R_{S T}\right) / n
$$

(Equation 32)
where n is the number of parallel circuits.
For the 100E series

```
1/ RE \geq
```

$$
\begin{gathered}
1 /\left(6.56^{*} \mathrm{Z} \mathrm{O} 1-\mathrm{RST} 1\right)+ \\
1 /\left(6.56^{*} \mathrm{Z}_{\mathrm{O} 2}-\mathrm{RST}_{2}\right)+ \\
1 /\left(6.56^{*} \mathrm{Z}_{03}-\mathrm{RST}_{\mathrm{S}}\right)
\end{gathered}
$$

For the case where

$$
\mathrm{Z}_{\mathrm{O} 1}=\mathrm{Z}_{\mathrm{O} 2}=\ldots \mathrm{Z}_{\mathrm{On}} \text { and } \mathrm{R}_{\text {ST } 1}=\mathrm{R}_{\mathrm{ST}}=\mathrm{RST}_{\mathrm{ST}}
$$

$$
\mathrm{R}_{\mathrm{E}} \leq\left(6.56{ }^{*} \mathrm{Z}_{\mathrm{O}}-\mathrm{R}_{\mathrm{ST}}\right) / \mathrm{n}
$$

(Equation 33)
where n is the number of parallel circuits.
When a series terminated line is driving more than a single ECL load the issue of maximum number of loads must be addressed. The factor limiting the number of loads is the voltage drop across the termination resistor caused by the input currents to the ECL loads when the loads are in the quiescent high state. A good rule of thumb is to determine if the loss in high state noise margin is acceptable. The loss in noise margin is given by

$$
\text { NMLOSS }=I_{T}{ }^{*}\left(R_{S T}+R_{O}\right)
$$

(Equation 34)

Figure 3.22. Noise Margin Loss Example
where:
IT = Sum of IINH Currents
For the majority of devices in the ECLinPS family the typical maximum value for quiescent high state input current
is $150 \mu \mathrm{~A}$. Thus, for the circuit shown in Figure 3.22, in which three gate loads are present in a $50 \Omega$ environment, the loss in high state noise margin is calculated as:

$$
\text { NMLOSS }=3^{*} 150 \mu \mathrm{~A} * 50 \Omega=22.5 \mathrm{mV}
$$

## ECLinPS I/O SPICE Modeling Kit

Due to the heavier reliance on simulation tools for initial prototyping, Motorola has put together a SPICE modeling kit aimed at aiding the customer in modeling board interconnect behavior. The kit includes representative drivers and receivers as well as the necessary SPICE model parameters. In addition, tips are provided for simulating a wide range of output conditions. The kit, in conjunction with today's CAD tools, can greatly simplify the design and characterization of critical nets in a design. Anyone interested in using SPICE for this purpose, is encouraged to read Application Note AN1503 located on page 5-69.

## SECTION 4 <br> Intefacing with ECLinPS

## Interfacing to Existing ECL Families

There currently exists two basic standards for high performance ECL logic devices: 10 H and 100K. To maximize system flexibility each member of the ECLinPS family is available in both of the existing ECL standards: 10E series devices are compatible with the MECL 10H family; 100E series devices are compatible with ECL 100K.

The difference in the DC behavior of the outputs of the two different standards necessitates caution when mixing the two technologies into a single ended input design. As illustrated in Figure 4.1 and Table 4.1, there is no problem when a 10 H device is used to drive a 100 K device; however, problems arise when the scenario is reversed.

For the case of a 100 K device driving a 10 H device, the worst case noise margin is reduced to 35 mV , a noise margin which is unacceptable for most designs. Since the problems of interfacing are an output tracking rate vs a $V_{B B}$ tracking rate problem, if the system uses only differential interconnect between the two technologies there will be no loss of noise margin and the design will operate as desired.

Fortunately, the ECLinPS family, by offering devices in both standards, allows the user to integrate higher performance technology into his design without having to battle these interface problems.

Another area of concern when interfacing to older, slower logic families, is the behavior of ECLinPS devices with slower input edge rates. Typically, other than clock inputs, the ECLinPS family will function properly for edge speeds of up to 20 ns . For edges significantly slower than 20 ns , the Schmitt trigger circuit of Figure 4.2 can be used to sharpen the edge rates reliably.

Obviously, a very slow edge rate will amplify differences in delay paths due to any offset of the $\mathrm{V}_{\mathrm{BB}}$ switching reference. This extra delay should be included in speed calculations of a design. For calculation purposes a worst case $\pm 200 \mathrm{ps} / \mathrm{hs}$

| Drvr $>$ Rcvr |  | NM - High |
| :---: | :---: | :---: |
| $10 \mathrm{H}>10 \mathrm{H}$ | 150 mV | 150 mV |
| $10 \mathrm{H}>100 \mathrm{H}$ | 145 mV | 125 mV |
| $100 \mathrm{H}>100 \mathrm{H}$ | 130 mV | 135 mV |
| $100 \mathrm{H}>10 \mathrm{H}$ | 35 mV | 130 mV |

Table 4-1. Worst-Case Noise Margins of a Mixed 10H and 100K Design
gate-gain delay (delay vs input edge rate) can be assumed or a more typical value of $\pm 75 \mathrm{ps} / \mathrm{ns}$ can be used.

5

Figure 4.1. Interfacing 10H ECL and 100K ECL
Clock inputs on flip-flop devices in the ECLinPS family are especially sensitive to slow edge rates. Flip-flops have been successfully clocked in a noise free bench setup environment with edge rates of up to 20 ns . However, in ATE systems where more noise is present, clocking problems arise with input edge rates of greater than 6.0 or 7.0 ns . To ensure reliable operation in a system with input clock edges slower than 7.0 ns , it is recommended that the signals be buffered
with an ECLinPS buffer circuit (E122, E116, E101, etc.) or, for extreme conditions, the Schmitt trigger of Figure 4.2 to provide the gain necessary to sharpen the edges on the clock pulse.

Figure 4.2. Schmitt Trigger w/100MV of Hysteresis

## Interfacing to TTL/CMOS Logic

To interface ECLinPS devices to TTL or CMOS subsystems there exists several new product offerings, as well as several existing devices, in the MECL 10KH family which are ideally suited to the task. These translation devices are specially suited for clock distribution, DRAM driving as well as general purpose translation in both single supply and dual supply environments. In mixed technology environments, it is recommended that the noisy supplies of TTL and CMOS circuits be isolated from the ECL supplies. This can be done either through separate power planes in the board or a common plane with isolated ECL and TTL power sub-planes. The planes of common voltages (i.e. ECL $V_{C C}$ and TTL ground for split supply systems or common $\mathrm{V}_{\mathrm{CC}}$ and ground for a single supply system) should then be connected to a common system ground or power supply through an appropriate edge connector.

## Interfacing to GaAs Logic

In general GaAs logic is designed to interface directly with ECL; however, in some instances, the worst case $\mathrm{V}_{\mathrm{OH}}$ of a GaAs output can go as high as -0.3V. An ECLinPS device, depending on the input structure, may become saturated when driven with a - 0.3 V signal. Application Note AN1404, on page $5-45$, deals exclusively with this phenomenon.

## AC Coupling

In some cases, it may be necessary to interface an ECLinPS design with a signal which lacks any DC offset.The differential devices in the ECLinPS family are ideally suited for this application. As pictured in Figure 4.3, the signal can be AC coupled and biased around the $V_{B B}$ switching reference of the device. Note that this scheme only works for a data stream with no DC bias, for data streams such as RZ or unencoded NRZ DC, restoration must be performed prior to AC coupling it to an ECLinPS device.

Figure 4.3. AC Couple Circuit

The $50 \Omega$ resistor of Figure 4.3 provides the termination impedance while the $\mathrm{V}_{\mathrm{BB}}$ pin provides the DC offset. The capacitor used to couple the signal must have an impedance of $\ll 50 \Omega$ for all frequency components of the input signal. Because large capacitors appear somewhat inductive at high frequencies, it may be necessary to use a small capacitor in parallel with a larger one to achieve satisfactory operation. In addition, it is important to bypass the $\mathrm{V}_{\mathrm{BB}}$ line when used in this manner to minimize the noise coupled into the device.

Because the $A C$ signal is biased around $V_{B B}$, the output of the ECLinPS device, when AC coupled, will have a duty cycle identical to the input. Thus, this type of application is ideal for transforming high frequency sinusoidal waveforms from an oscillator into a square wave with a $50 \%$ duty cycle. The E416 device is a specialized line receiver with a much higher bandwidth than alternative ECLinPS devices; therefore, for frequencies of $>500 \mathrm{MHz}$, it is recommended that the designer use this device.

The above mentioned scenario will work fine as long as the input signal is present, however, if the the inputs to the AC coupled device are left open, problems may occur. With no input signal both inputs will go to $\mathrm{V}_{\mathrm{BB}}$ and an undefined output, and perhaps, an oscillating output, will result. If a defined output is necessary for an open input scenario, the circuit of Figure 4.4 can be used. The resistor tree between $V_{C C}$ and $V_{B B}$ creates an offset between the two inputs so that if the driving signal is lost, a stable defined output will occur.

Figure 4.4. AC Couple Circuit with DC Offset

Unfortunately, this configuration will adversely affect the duty cycle of the output. Depending on the frequency of the output, the duty cycle will change due to the longer distance to threshold on a rising edge as opposed to a falling edge. With this in mind, it becomes obvious that the smallest feasible offset would be the best solution. For stability, a minimum of 25 mV is recommended, however, this will not produce full ECL levels at the outputs of an E116 and, thus, another differential gate should be used to further amplify the signal. The gain of the E416, on the other hand, is sufficient to produce acceptable levels at the outputs for DC input voltage differences of 25 mV . If a 150 mV offset is used, full ECL levels will be seen at the outputs of the E116, however, the price in duty cycle skew will be high. Of course, if the signal is divided after it is received, the duty cycle will be restored.

When using the circuit of Figure 4.4 care should be taken to limit the current sunk by the $\mathrm{V}_{\mathrm{BB}}$ pin to a maximum of 0.5 mA . To achieve an offset of greater than 25 mV for the circuit of Figure 4.4, the DC current will necessarily need to be greater than 0.5 mA . To alleviate this dilemma, one of the gates of the E116 can be configured as pictured in Figure 4.5 to generate a $\mathrm{V}_{\mathrm{BB}}$ reference with the necessary current sinking capability. A single gate configured in this way will source or sink up to 10 mA without a significant shift in the
generated $\mathrm{V}_{\mathrm{BB}}$ level. If more current is needed, several gates can be connected in parallel to provide the extra drive capability.

Note that the circuit pictured in Figure 4.4 will result in the Q outputs going high when the inputs are left open. If the opposite is desired, the resistor to $\mathrm{V}_{\mathrm{CC}}$ can be tied to the inverting input and $\mathrm{V}_{\mathrm{BB}}$ to the non-inverting input.

Figure 4.5. High Current VBB $_{\text {Benerator }}$

# SECTION 5 <br> Package and Thermal Information 

## Package Choice

ECLinPS is offered in the 28-lead plastic leaded chip carrier (PLCC) package, a leaded surface mount IC package. The lead form is of the "J-lead" type. For detailed dimensions of the 28 -lead PLCC refer to the package description drawings at the end of this section.

The PLCC was selected as the optimum combination of performance, physical size and thermal handling in a low cost standard package. While more exotic packages exist to improve these qualities still further, the cost of these is prohibitive for many applications.

The PLCC features considerably faster propagation delay and reduced parasitics compared to a DIP package of similar pin-count; two properties that make it eminently suitable for very high performance logic.

The 28-lead PLCC for the ECLinPS family is available in tape and reel form to further facilitate automatic pick and place. The characteristics of the 28 -lead PLCC reel are described in Figure 5.1 below.

Figure 5.1. 28-Lead PLCC Tape \& Reel Information

Orders must be full reels or multiples of full reels as no partial reels will be shipped. An R2 suffix has been established to add to the end of the part number to signify the desire for tape and reel product. Therefore, to order the MC10E111FN in tape and reel the part number would become MC10E111FNR2.

## Reliability of Plastic Packages

Although today's plastic packages are as reliable as ceramic packages under most environmental conditions, as the junction temperature increases a failure mode unique to plastic packages becomes a significant factor in the long term reliability of the device.

Modem plastic package assembly utilizes gold wire bonded to aluminum bonding pads throughout the electronics industry. As the temperature of the silicon (junction temperature) increases, an intermetallic compound forms between the gold and aluminum interface. This intermetallic formation results in a significant increase in the impedance of the wire bond and can lead to performance failure of the affected pin. With this relationship between intermetallic formation and junction temperature established, it is incumbent on the designer to ensure that the junction temperature for which a device will operate is consistent with the long term reliability goals of the system.

Reliability studies were performed at elevated ambient temperatures $\left(125^{\circ} \mathrm{C}\right)$ from which an arrhenius equation, relating junction temperature to bond failure, was established. The application of this equation yields the table of Figure 5.2. This table relates the junction temperature of a device in a plastic package to the continuous operating time before $0.1 \%$ bond failure (1 failure per 1000 bonds)

ECLinPS devices are designed with chip power levels that permit acceptable reliability levels, in most systems, under the conventional $500 \mathrm{lfpm}(2.5 \mathrm{~m} / \mathrm{s})$ airflow.

## Thermal Management

As in any system, proper thermal management is essential to establish the appropriate trade-off between performance, density, reliability and cost. In particular, the designer should be aware of the reliability implication of continuously operating semiconductor devices at high junction temperatures.

The increasing popularity of surface mount devices (SMD) is putting a greater emphasis on the need for better thermal management of a system. This is due to the fact that SMD packages generally require less board space than their through hole counterparts so that designs incorporating SMD technologies have a higher thermal density. To optimize the thermal management of a system it is imperative that the user understand all of the variables which contribute to the junction temperature of the device.
$T=6.376 \times 10-9 \mathrm{e}\left[\frac{11554.267}{273.15+\mathrm{TJ}}\right]$
Where:
$\mathrm{T}=$ Time to $0.1 \%$ bond failure

| Junction <br> Temp. $\left({ }^{\circ} \mathbf{C}\right)$ | Time (Hrs.) | Time (yrs.) |
| :---: | :---: | :---: |
| 80 | $1,032,200$ | 117.8 |
| 90 | 419,300 | 47.9 |
| 100 | 178,700 | 20.4 |
| 110 | 79,600 | 9.1 |
| 120 | 37,000 | 4.2 |
| 130 | 17,800 | 2.0 |
| 140 | 8,900 | 1.0 |

Figure 5.2 Tj vs Time to $0.1 \%$ Bond Failure
The variables involved in determining the junction temperature of a device are both supplier and user defined. The supplier, through lead frame design, mold compounds, die size and die attach, can positively impact the thermal resistance and, thus, the junction temperature of a device. Motorola continually experiments with new package designs and assembly techniques in an attempt to further enhance the thermal performance of its products.

It can be argued that the user has the greatest control of the variables which commonly impact the thermal performance of a device. Ambient temperature, air flow and related cooling techniques are the obvious user controlled variables, however, PCB substrate material, layout density, size of the air-gap between the board and the package, amount of exposed copper interconnect, use of thermally-conductive epoxies and number of boards in a box, can all have significant impacts on the thermal performance of a system.

PCB substrates all have different thermal characteristics, these characteristics should be considered when exploring the PCB alternatives. The user should also account for the different power dissipations of the different devices in his system and space them on the PCB accordingly. In this way, the heat load is spread across a larger area and "hot spots" do not appear in the layout. Copper interconnect traces act as heat radiators, therefore, significant thermal dissipation can be achieved through the addition of interconnect traces on the top layer of the board. Finally, the use of thermally conductive epoxies can accelerate the transfer of heat from the device to the PCB where it can more easily be passed to the ambient.

The advent of SMD packaging and the industry push towards smaller, denser designs makes it incumbent on the designer to provide for the removal of thermal energy from the system. Users should be aware that they control many of the variables which impact the junction temperatures and, thus, to some extent, the long term reliability of their designs.

## Calculating Junction Temperature

The following equation can be used to estimate the junction temperature of a device in a given environment:

$$
T J=T_{A}+P_{D} \Theta J A
$$

where:
TJ = Junction Temperature
$\mathrm{T}_{\mathrm{A}}=$ Ambient Temperature
PD = Power Dissipation
$\Theta J A=$ Avg Pkg Thermal Resistance (Junction Ambient)
The power dissipation factor is made up of two elements: the internal gate power and the power associated with the output terminations. Essentially, the two contributors can be calculated separately, then added to give the total power dissipation for a device.

To calculate the power of the internal gates the user simply multiplies the $\mathrm{I}_{\mathrm{EE}}$ of the device times $\mathrm{V}_{E E}$. Since $\mathrm{I}_{E E}$ in $E C L$ is a constant parameter, frequency need not be factored into the calculations. A worst case or typical number for chip power can be calculated by using either worst case or typical data book values for the IEE and VEE of a device.

Next, the power of the outputs needs to calculated so that the total power dissipation for a device can be determined. The output power is dependent on the termination resistance and the termination scheme used to pulldown the outputs. The most typical termination scheme for ECLinNPS designs is a parallel termination into -2.0 V . For this scheme, the following equation describes the power for a single output of the device:

$$
\text { PDOUT = IOUT * VOUT = (VOUT - (-2)) RT* }{ }^{*} V_{\text {OUT }}
$$

where:

$$
\begin{array}{ll}
\mathrm{V}_{\mathrm{OUT}} & =\mathrm{V}_{\mathrm{OH}} \text { or } \mathrm{V}_{\mathrm{OL}} \\
\mathrm{RT} & =\text { Termination Resistance }
\end{array}
$$

The power dissipated in the output of a device is dependent on the duty cycle of that output. For an output terminated to $\mathrm{V}_{\mathrm{TT}}$ the worst case situation would be if the output was in the high state all of the time, for an output terminated to $\mathrm{V}_{\mathrm{EE}}$ the low state will represent worst case. For single ended output devices, typically the power is calculated with the outputs in the worst case and for a $50 \%$ duty cycle. For differential outputs, the power for a differential pair is constant since they are always in complimentary states, therefore, for a given output, the power will simply be the average of the high and low state output powers. Figure 5.3 shows the various output power levels for the different output types and conditions. In addition, the table includes power numbers for various other termination resistances and alternative termination schemes. These numbers can be derived by determining the IOUT and VOUT for the different alternatives and applying the equation above.

| Termination Resistance | Output Power (mW) |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | Differential Output |  | Single-ended Output (50\%) Duty Cycle) |  | Single-ended Output (Worst Case) |  |
|  | 10E | 100E | 10E | 100E | 10E | 100E |
| 50 to -2.0V | 14.3 | 15.0 | 14.3 | 15.0 | 19.8 | 20.0 |
| 68 to -2.0V | 10.5 | 11.1 | 10.5 | 11.1 | 14.6 | 14.7 |
| 100 to -2.0V | 7.1 | 7.5 | 7.1 | 7.5 | 9.9 | 10.0 |
| 510 to - 5.2 V | 9.7 | 9.8 | 9.7 | 9.8 | 11.8 | 11.7 |
| 330 to -5.2V | 15.0 | 15.1 | 15.0 | 15.1 | 18.3 | 18.0 |
| 180 to - 5.2 V | 27.5 | 27.8 | 27.5 | 27.8 | 33.5 | 33.1 |
| 510 to - 4.5V | - | 7.8 | - | 7.8 | - | 9.3 |
| 330 to -4.5V | - | 12.3 | - | 12.3 | - | 14.4 |
| 180 to - 4.5 V | - | 22.6 | - | 22.6 | - | 26.4 |

Figure 5.3 Output Power for Various Termination Schemes

Now that the power dissipation of a device can be calculated, one needs to determine which level of the parameter (i.e. typical, max, etc..) to use to estimate the long term reliability of the system. Since this number is statistical in nature, simply applying the worst case numbers will be overly pessimistic as these parameters vary statistically themselves. It is not very likely, for instance, that every device type will be operating at the maximum specified IEE level. Assuming all worst case conditions can have a significant impact on the resulting junction, temperature estimates leading to erroneous conclusions about the reliability of the design.

Another important parameter for calculating the junction temperature of a device is the junction-ambient thermal
resistance, $\Theta \mathrm{JA}$, of the package. $\Theta \mathrm{JA}$ is expressed in ${ }^{\circ} \mathrm{C}$ per watt ( ${ }^{\circ} \mathrm{C} / \mathrm{W}$ ) and is used to determine the temperature elevation of the die (junction) over the external package ambient temperature. Standard lab measurements of this parameter for the 28 -lead PLCC yields the graph of Figure 5.4.

An alternative calculation scheme for $\mathrm{T}_{J}$ substitutes the case temperature ( $\mathrm{T}_{\mathrm{C}}$ ) and the junction-to-case ( $\Theta_{\mathrm{JC}}$ ) thermal resistance for their ambient counterparts in the $T_{J}$ equation previously mentioned. The $\Theta_{J C}$ for the 28 -lead PLCC is $32^{\circ} \mathrm{C} / \mathrm{W}$. This parameter is measured by submerging the device in a liquid bath and measuring the temperature of the bath, therefore, it represents an average case temperature.

| Air Flow (fpm) | $\Theta_{(J A)}\left({ }^{\circ} \mathbf{C} / \mathbf{W}\right)$ |
| :---: | :---: |
| 0 | 63.5 |
| 125 | 52 |
| 250 | 48 |
| 500 | 43.5 |
| 1000 | 38 |

Figure 5.4. Thermal Resistance vs Air Flow for the 28-lead PLCC

The difficulty in using this method arises in the determination of the case temperature in an actual system. The case temperature is a function of the location at which the temperature is measured on the package. Therefore, to use the $\Theta_{J C}$ mentioned above, the case temperature would have to be measured at several different points and averaged to represent the $\mathrm{T}_{\mathrm{C}}$ of the device. This, in practice, could prove difficult and relatively inaccurate.

## Junction Temperature Calculation Example

As an example, the power dissipation for a 10E151, 6-bit register function, will be calculated for 500 Ifpm airflow; both a worst case number and a typical number will be calculated. From the data sheet the typical and maximum IEE's for the device are 65 mA and 85 mA respectively. There are six differential output pairs.

```
Chip Power =
    65mA * 5.2V=338mW typical
    85mA * 5.46V = 464mW worst case
Output Power =
    ((-1.75-(-2))/50*1.75 + (-0.9 (-2))/50*0.9))/2 =
    14.3mW
```

Total Power Pd =
$338 \mathrm{~mW}+14.3^{*} 12=510 \mathrm{~mW}$ typical
$464 \mathrm{~mW}+14.3^{*} 12=635 \mathrm{~mW}$ worst case

Junction Temperature $=$
$\mathrm{T}_{\mathrm{A}}+43.5^{\circ} \mathrm{C} / \mathrm{W}^{*} 0.510 \mathrm{~W}=\mathrm{T}_{\mathrm{A}}+22^{\circ} \mathrm{C}$ typical
$\mathrm{T}_{\mathrm{A}}+43.5^{\circ} \mathrm{C} / \mathrm{W}^{*} 0.635 \mathrm{~W}=\mathrm{T}_{\mathrm{A}}+28^{\circ} \mathrm{C}$ worst case
Note that in this case, the worst case junction temperatures are not significantly larger than the typical case. This is due mainly to the fact that the device has differential outputs. A higher IEE, single ended device would show a much larger discrepancy between the worst case and typical values.

## Limitations to Calculation Technique

The use of the previously described technique for estimating junction temperatures is intimately tied to the measured values of the ©JA of the 28-lead PLCC package. Since this parameter is a function of not only the package, but also the test fixture, the results may not be applicable for every environmental condition. The 28 -lead PLCC test fixture used was a $2.24^{\prime \prime} \times 2.24^{\prime \prime} \times 0.062^{\prime \prime}$, FR4 type, glass epoxy board with 1 oz . copper used for interconnects. The copper represented about $50 \%$ coverage of the test fixture.

If the user's actual application does not come close to approximating this situation it may be necessary to use a different method for determining the junction temperature of a device. An empirical equation relating junction temperature to the actual case temperature and lead temperature of a device has been established. This equation has the advantage of being universal for all environmental conditions, however, the disadvantage of having to make
actual thermocouple temperature measurements may limit its use.

The equation describing the junction temperature is as follows:

$$
\mathrm{T}_{\mathrm{J}}=24 \mathrm{P}_{\mathrm{D}}+0.313 \mathrm{~T}_{\mathrm{C}}+0.687 \mathrm{~T}_{\mathrm{L}}{ }^{\circ} \mathrm{C} / \mathrm{W}\left( \pm 2^{\circ} \mathrm{C} / \mathrm{W}\right)
$$

where:

```
pD = Power Dissipation of the Device (W)
\(\mathrm{T}_{\mathrm{C}}=\) Case Temperature \(\left({ }^{\circ} \mathrm{C}\right)\)
\(\mathrm{T}_{\mathrm{L}}=\) Lead Temperature \(\left({ }^{\circ} \mathrm{C}\right)\)
```

$\mathrm{T}_{\mathrm{C}}$ is measured at the top-center surface of the package, taking care that the thermocouple makes good contact with the case without transporting a significant amount of heat from the measurement point. The lead temperature is used to compensate for the differences in the ratio of heat transfer through the leads and the top surface of the package. This difference impacts the actual $\mathrm{T}_{\mathrm{C}}$ of the package. As mentioned earlier, this method of determining the junction temperature is effective for almost all environmental conditions except those that incorporate an external heatsink. Of all the techniques mentioned in this document, the application of this equation will lead to the most accurate assessment of the junction temperature of a device.

## Heatsinks

A plastic fin type heatsink recently developed by EG\&G Engineering for a 40-lead PLCC was modified to fit the 28-lead

5

## Package and Thermal Information

PLCC and evaluated. The addition of the heatsink showed a decrease of $20^{\circ} \mathrm{C} / \mathrm{W}$ in the thermal resistance of the 28-lead PLCC in a natural convection air flow environment. The test device was suspended in air to simulate a dense board application where minimal heat will transfer from the device to the PCB substrate.

For more detailed information on availability and performance of heatsinks the user is encouraged to contact the numerous heatsink vendors.

## Package Dimensions

Figure 5.5 on the previous page provides recommended printed circuit board solder pad dimensions for several PLCC packages. With this information and the 28 -lead PLCC dimensions provided in Figure 5.6, the system designer should have all of the information necessary to successfully mount 28-lead PLCC packages on a surface mount PCB.

# SECTION 6 Quality \& Reliability 

## Quality

The Motorola culture is a culture of quality. Throughout all phases of product development, from defining and designing to shipping the product, Motorola strives for total customer satisfaction through "Six Sigma" and "On Time Delivery" programs.

## Defining Products

From the beginning, the goal of the ECLinPS family was to be "customer" defined. Extensive work was done up front to identify part types which were perfectly suited to the needs of our customers. This definition phase ensured a level of quality for the family in that the customer defines the product rather than the supplier dictating product types.

## Designing Products

Superior quality products start with the design, and the design of a product starts with an IC process. Extensive work was done with the MOSAIC III process to ensure a solid platform for quality products. Process reliability studies were performed to uncover any weaknesses in the initial process so that enhancements could be made to strengthen it before it was released to production. In addition, comprehensive characterization and correlation work was completed on the process to ensure the utmost in modeling parameter accuracy.

The design of the products strictly adhered to the design rules set forth by the process designers. Conservative, manufacturable layout rules were followed to minimize the performance variability due to a marginally manufacturable product. In addition, the use of statistical modeling methods, such as factorial and response surface techniques, in the designing of the IC's leads to products with a reduced sensitivity to variations in the manufacturing process.

## Manufacturing Process

Through SPC and continual engineering work, the manufacture of the MOSAIC III process is both monitored and enhanced on a continuous basis. Statistical data is gathered at both probe and final test through the device data collection to monitor the distribution of a parameter to its specification limits. In addition, final quality assurance gates are set up to guarantee the quality of outgoing product.

## Product Characterization

Products are both DC and AC characterized for all data book environmental conditions prior to the release of the product to production. The distributions of the parameters are
compared to their specification limits to ensure that Motorola "manufactures" quality products as opposed to "testing" quality products through distribution truncation. In addition, ongoing AC characterization is performed to enhance the distributions of the AC parameters of the device. In doing so, as the distributions warrant, further enhancements to the AC specifications can be achieved.

## Reliability

To ensure the long term reliability of ECLinPS products, extensive accelerated life testing is performed prior to production release. This qualification work is performed by Logic Reliability Engineering, an organization specifically dedicated to monitoring and guaranteeing the quality and and reliability of logic products. The accelerated life test consists of the following:

Operating Life Test: $145^{\circ} \mathrm{C}$ Mil. Std. 883
Temperature Cycle: $-65^{\circ} \mathrm{C}$ to $150^{\circ} \mathrm{C}$ Mil. Std. 883
Pressure, Temperature, Humidity (Hermeticity)
A minimum of two lots, 250 die per lot taken from three different waters in the lot constitute a qualification sample. Various intermediate readouts are taken to monitor the performance more closely. In addition, the devices are tested beyond the specification limits to determine where and how they will fail.

Another responsibility of the reliability group is that of failure analysis. This failure analysis service is supported for both internal purposes and for servicing the needs of our customers. Analysis entails everything from simple package examination to internal microprobing to SEM analysis of IC structures. The results of the analysis are returned to the customer and if the analysis suggests a potential problem with the device the information is also passed to the internal product groups.

## RAP: Reliability Audit Program

The Reliability Audit Program (RAP) devised in March 1977 is the Motorola internal reliability audit which is designed to assess outgoing product performance under accelerated stress conditions. Logic Reliability Engineering has overall responsibility for RAP, including updating its requirements, interpreting its results, administration at offshore locations and monthly reporting of results. These reports are available at all sales offices. Also available is the "Reliability and Quality Handbook" which contains data for all Motorola semiconductors (BR518/D).

## Quality \& Reliability

Rap is a system of environmental and electrical tests performed periodically on randomly selected samples of standard products. Each sample receives the tests specified
in Figure 6.1. Frequency of testing is specified per internal document 12MRM15301A.

Figure 6.1. Reliability Audit Program Test Flow

* PTH will be run as a substitute if PTHB sockets are not available. Only required on plastics packages.
** Thermal Shock will be run if Temp Cycle is not available.
*** Seal (fine and gross) only required on hermetic packages.
**** All units for Op Life to be AC/DC tested before and after being stressed. All units failing AC after stress will be analyzed.
***** One sample per month

PTHB
$15 \mathrm{psig} / 121^{\circ} \mathrm{C} / 100 \% \mathrm{RH}$ at rated $\mathrm{V}_{\mathrm{CC}}$ or $\mathrm{V}_{\mathrm{EE}}$ - to be performed on plastic encapsulated devices only.

## Temp Cycle

Mil. Std. 883 , Method 1010 , Condition $\mathrm{C},-65^{\circ} \mathrm{C}$ to $150^{\circ} \mathrm{C}$

## Op Life

Mil. Std. 883, Method 1005, Condition C (Power plus Reverse Bias), $\mathrm{T}_{\mathrm{A}}=145^{\circ} \mathrm{C}$.

## Notes:

1. All standard $25^{\circ} \mathrm{C}$ DC and functional parameters will be measured $\mathrm{Go} / \mathrm{NoGo}$ at each readout.
2. Any indicated failure is first verified and then submitted to the Product Analysis Lab for detailed analysis.
3. Sampling to include all package types routinely.
4. Device types sampled will be by generic type within each digital IC product family (MECL, TTL, etc.) and will include all assembly locations (Korea, Phillipines, Malaysia, etc.).
5. 16 hrs. PTHB is equivalent to $\approx 800 \mathrm{hrs}$. of $85^{\circ} \mathrm{C} / 85 \%$ RH THB for $\mathrm{V}_{\mathrm{CC}} \leq 15 \mathrm{~V}$.
6. Only moisture related failures (like corrosion) are criteria for failure on PTHB test.
7. Special device specifications (48A's) for digital products will reference 12MRM15301A as a source of generic data for any customer requiring monthly audit reports.

# ECLinPSTM Circuit Performance at Non-Standard VIH Levels 

Prepared by
Todd Pearson
ECL Applications Engineering

This application note explains the consequences of driving an ECLinPS device with an input voltage HIGH level $\left(V_{I H}\right)$ which does not meet the maximum voltage specified in the ECLinPS Databook.

MOTOROLA

## ECLinPS Circuit Performance at Non-Standard VIH Levels

## Introduction

When interfacing ECLinPS devices to various other technologies times arise where the the input voltages do not meet the specification limits outlined in the ECLinPS data book. The purpose of this document is to explain the consequences of driving an ECLinPS device with an input voltage HIGH level $\left(\mathrm{V}_{\mathrm{IH}}\right)$ which does not meet the maximum voltage specified in the ECLinPS Databook.
The results outlined in this document should not be viewed as guarantees by Motorola but rather as representative information from which the reader can base design decisions. It is up to the reader to assess the risks of implementing the non-standard interface and deciding if that level of risk is acceptable for the system design. Motorola's guarantee on $\mathrm{V}_{\mathrm{IH}}$ will continue to be the specification standards established for the $10 \mathrm{H}^{T M}$ and 100 K ECL technologies.

## Overview

The upper end of the $\mathrm{V}_{\mathrm{IH}}$ spec of an ECLinPS, or any other ECL, input is limited by saturation affects of the input transistor. Figure 1 below illustrates a typical ECL input (excluding pulldown resistors and ESD structures); the structure is a basic differential amplifier configuration. With a logic HIGH level asserted at the input the collector of that transistor will be pulled down below the $\mathrm{V}_{\mathrm{CC}}$ rail by the gate current passing through the collector load resistor. The voltage at the collector of the input transistor $\left(\mathrm{V}_{\mathrm{C}}\right)$ will be dependent on the gate current and the size of the collector load resistor associated with the input gate.

Figure 1. Typical ECLinPS Input Structure

As the input $\mathrm{V}_{\mathrm{IH}}$ increases towards $\mathrm{V}_{\mathrm{CC}}$ the collector base junction of the input transistor becomes forward biased; as this forward bias condition increases the transistor will move into the saturation region. The value of $\mathrm{V}_{\mathrm{CB}}$ at which the transistor begins to saturate is process dependent and will vary from logic family to logic family. Fortunately the MOSAIC III process used to implement the ECLinPS family incorporates a deep n+ collector doping. This deep collector helps to mitigate the effects of saturation of transistors by requiring a larger
collector-base forward bias to enter the saturation region.

## $\mathrm{V}_{\text {IH }}$ max and the ECLinPS Family

As previously mentioned the MOSAIC IIITM process allows for ECLinPS devices to operate at $\mathrm{V}_{\text {IH }}$ max levels somewhat higher than those specified in the databook, however the exact value of $\mathrm{V}_{\mathrm{IH}}$ for which saturation problems will occur varies from device to device and even among different inputs for a given device. This variation is a result of the different input configurations used on the various inputs of ECLinPS devices.

The easiest way to define an acceptable $\mathrm{V}_{\text {IH }}$ max for each device in the family is to define at what point the input transistor will saturate and specify for each input what the worst case input transistor collector voltage will be. With this information designers will be able to determine on a part by part, input by input basis what input voltage levels will be acceptable for their application.

## Simulation Results

The input saturation phenomenon was characterized through SPICE simulations and the results will be reported in the following text. For simplicity of simulation a buffer similar to the E122 was used. Since the outputs of this buffer drive off chip, the $\mathrm{V}_{\text {IH }}$ max performance of this structure will be worse than the typical input structure. Both a 100 K and a 10 H style buffer were analyzed to note any discrepancies between the two standards. As expected the simulation results showed no difference in the saturation susceptibility of a 100 K versus a 10 H style buffer. Therefore the simulation results of only the 100K style buffer will be presented to minimize redundancy of information.

The following text will refer to Figures 4-8 in the appendix of this document. Figures $4-8$ are graphical plots of the input and output waveforms of an E122 style buffer (structure similar to that of Figure 1) for various $\mathrm{V}_{\mathrm{IH}}$ levels. V (in) represents the input voltage while $\mathrm{V}(\mathrm{q})$ and $\mathrm{V}(\mathrm{qb})$ represent the output voltages. The $\mathrm{V}(\mathrm{vbb})$ line was included for measurement purposes only and will be ignored.

Figure 4 represents the "standard" operation of the device as a standard $\mathrm{V}_{\mathrm{IH}}$ input was used. Note that in this condition the propagation delays measure in the 215-225ps range and the IINH was $42.5 \mu \mathrm{~A}$. The IINH of this device is simply a measure of the base current of the input transistor when that transistor is conducting current. We will be monitoring both of these conditions as well as any degradation in the output waveforms as a sign of the input transistor becoming saturated. As can be seen in Figures 5 and 6 none of the parameters change for $\mathrm{V}_{\mathrm{IH}}$ levels of up to -0.4 V . With a collector voltage, $\mathrm{V}_{\mathrm{C}}$, of -1.0 V these $\mathrm{V}_{\text {IH }}$ 's correspond to a collector base forward bias of 600 mV . As the $\mathrm{V}_{\mathrm{IH}}$ of the input moves closer to $\mathrm{V}_{\mathrm{CC}}$, Figures 7 and 8, three phenomena start to occur: the liNH increases, the delays increase and significant changes occur to the output low level of the QB pin.

In Figure 7 the liNH of the input transistor has more than doubled from the "standard" level. This increase in base current leads to an increase in the $\mathrm{V}_{\mathrm{OL}}$ level as the collector current must reduce to maintain the constant emitter current. As the collector current reduces, the IR drop across the collector load resistor reduces, thus raising the $\mathrm{V}_{\mathrm{OL}}$ level on the QB output. Although the $\mathrm{V}_{\mathrm{OL}}$ level has shifted the overall propagation delay has remained essentially unchanged.

Finally, when the input is switched all the way up to $\mathrm{V}_{\mathrm{CC}}$ the $V_{\text {OL }}$ level no longer remains in spec as the input base current has jumped to almost 1 ma and there has been significant degradation in the high-low propagation delay. It is apparent that for this condition an E122 style buffer will not perform adequately for most systems.

From this information it can be concluded that for a collector-base forward bias of $\leq 600 \mathrm{mV}$ there will be no adverse conditions on the performance of the device. The performance starts to degrade with further forward bias until at a forward bias voltage of $\approx 1.0 \mathrm{~V}$ the device will fail both its DC and $A C$ specifications.

## ECLinPS Input Structures

There are four basic input structures which will affect the $\mathrm{V}_{\text {IH }}$ max performance of ECLinPS devices. The four structures are as follows: an internal buffer, an external buffer, an emitter follower input buffer and a series gated emitter follower input.
The internal buffers are input structures whose outputs drive other gates internal to the device, the voltage swings of the input transistor collectors $\left(\mathrm{V}_{\mathrm{C}}\right)$ on these devices will be $\approx 800 \mathrm{mV}$. An external buffer is one in which the outputs are fed external to the chip. Because of the relatively large base drive of the output emitter follower for these structures the $\mathrm{V}_{\mathrm{C}}$ voltage will typically be a couple hundred milivolts lower than for the internal buffer. Note that because of the larger output swings of a 10E device, a 10E style external buffer will require a $\mathrm{V}_{\text {IH }}$ max input level more near the specified value. Both of these structures are similar to that pictured in Figure 1.
The third and fourth structures are somewhat different in design than the first two. Figure 2 illustrates an emitter follower input structure. For the basic emitter follower input the

input voltages are dropped by an additional $\mathrm{V}_{\mathrm{BE}}(\approx 800 \mathrm{mV})$ before they are fed into the differential amplifier input gate. The switching reference is also shifted down by one diode drop to remain centered in the input swing. Obviously this input structure will represent the "best case" in the area of extended $\mathrm{V}_{\text {IH }}$ max performance. In fact this type of input structure will allow for input voltages even several hundred millivolts above the $\mathrm{V}_{\mathrm{CC}}$ rail. This characteristic makes these type devices ideal for interfacing with differential oscillators whose outputs lack any DC offset. In the emitter follower structure the limiting factor will be the saturation of the emitter follower device whose collector is at $\mathrm{V}_{\mathrm{CC}}$. From the previous simulation results this would suggest a maximum $\mathrm{V}_{\mathrm{IH}}$ of +0.6 V .

Figure 2. Emitter Follower Input Structure
The series gate emitter follower input will represent the absolute worst case situation for a 100E device. Figure 3 represents a series gate emitter follower input for a 10E and a 100E device. From this figure it is apparent that the lower switching level ( $B$ input level) is going to be much more susceptible to $\mathrm{V}_{\text {IH }}$ max for the 100E device than the 10E device. The two diode drops used for the 10E device is not possible for a 100E device due to the smaller VEE voltage of a 100E device.

To summarize the external gate will represent the worst case $\mathrm{V}_{\mathrm{IH}} \max$ situation for a 10 E device while the series gate emitter follower case will represent worst case for a 100E device. In either situation the standard emitter follower will allow the most leeway for non-standard $\mathrm{V}_{\mathrm{IH}}$ max performance.

## Other Considerations

When driving ECLinPS devices with other than standard input levels there is another phenomena that should be considered; namely effects of non-centered switching references on the AC performance of a device. For non-standard input voltages the midpoint of the voltage swing may not correspond to the internal $\mathrm{V}_{\mathrm{BB}}$ switching reference. If this is the case the resulting AC variation should be included in the evaluation of a design.
An input voltage swing not centered about the switching reference will exhibit a delay skew between the two input edge transitions. The size of this skew will be dependent on both the voltage offset of the reference voltage and the midpoint of the input swing and the slew rate of the input as it passes through the threshold region. As an example for the case in which the $\mathrm{V}_{\mathrm{IH}}=-0.5 \mathrm{~V}$ and the $\mathrm{V}_{\mathrm{IL}}$ remains at -1.7 V the midpoint of the swing will be at -1.1 V versus $\mathrm{a}-1.32 \mathrm{~V} \mathrm{~V}_{\mathrm{BB}}$ reference. With a typical slew rate of $1 \mathrm{ps} / \mathrm{mV}$ for ECLinPS type edge rates the rising input edge delay will be 220ps longer than normal and the falling edge delay will be 220ps faster. This results in a 440ps skew between the two input transitions that would not be seen for an ideal switching reference.

The only means of correcting this skew is to lower the $\mathrm{V}_{\mathrm{IL}}$ level to recenter the swing or provide a different switching reference for the device. The latter can be accomplished by buffering the signal with a differential input device with one input tied to an externally generated switching reference. Raising the $\mathrm{V}_{\text {IL }}$ level is not recommended due to the obvious loss of low end noise margin accompanied by any such shift.

## Conclusions

Simulations show that forward bias levels of $\leq 600 \mathrm{mV}$ on the input transistor will keep the input transistor in the active region and the performance of the device will not be compromised. This forward bias voltage can be increased with varying degrees of performance degradation to levels somewhat higher than 600 mV . Initial effects will be an increase in the liNH current and a decrease in the output $\mathrm{V}_{\mathrm{OL}}$ level on the QB output of the input gate. As the forward bias increases further the propagation delays through the device will be adversely affected.

The following example will outline the use of the table in the appendix to analyze the potential performance of a design using non-standard $\mathrm{V}_{\mathrm{IH}}$ levels. If a design called for the 10E112 and the 10E416 to be driven by a -0.2 V input signal a designer would want to know if these two devices would perform to specifications under these conditions. From the table the worst case collector voltage $\mathrm{V}_{\mathrm{C}}$ would be -1.05 V and 0.0 V respectively. Subtracting these values from -0.2 V yields forward bias voltages of 850 mV and -200 mV respectively. From this information the designer would conclude that the 10E416 will function with no problems however the 10E112 could suffer performance degradation under these same conditions.
The device information contained in the appendix of this document will provide designers with all of the information necessary to evaluate the input transistor forward bias conditions for all of the ECLinPS devices for different input voltages. With these numbers and the information provided in this document designers will be able to make informed decisions about their designs to meet the performance desired at an acceptable level of risk.

# ECL Clock Distribution Techniques 

Prepared by
Todd Pearson
ECL Applications Engineering

This application note provides information on system design using ECL logic technologies for reducing system clock skew over the alternative CMOS and TTL technologies.

## ECL Clock Distribution Techniques

## INTRODUCTION

The ever increasing performance requirements of today's systems has placed an even greater emphasis on the design of low skew clock generation and distribution networks. Clock skew, the difference in time between "simultaneous" clock transitions within a system, is a major component of the constraints which form the upper bound for the system clock frequency. Reductions in system clock skew allow designers to increase the performance of their designs without having to resort to more complicated architectures or more costly, faster logic. ECL logic technologies offer a number of advantages for reducing system clock skew over the alternative CMOS and TTL technologies.

## SKEW DEFINITIONS

The skew introduced by logic devices can be divided into three parts: duty cycle skew, output-to-output skew and part-to-part skew. Depending on the specific application, each of the three components can be of equal or overriding importance.

## Duty Cycle Skew

The duty cycle skew is a measure of the difference between the TPLH and TPHL propagation delays (Figure 1). Because differences in TPLH and TPHL will result in pulse width distortion the duty cycle skew is sometimes referred to as pulse skew. Duty cycle skew is important in applications where timing operations occur on both edges or when the duty cycle of the clock signal is critical. The later is a common requirement when driving the clock inputs of advanced microprocessors.

Figure 1. Duty Cycle Skew

## Output-to-Output Skew

Output-to-output skew is defined as the difference between the propagation delays of all the outputs of a device. A key constraint on this measurement is the requirement that the output transitions are identical, therefore if the skew between all edges produced by a device is important the output-to-output skew would need to be added to the duty cycle skew to get the total system skew. Typically the
output-to-output skew will be smaller than the duty cycle skew for TTL and CMOS devices. Because of the near zero duty cycle skew of a differential ECL device the output-to-output skew will generally be larger. The output-to-output skew is important in systems where either a single device can provide all of the necessary clocks or for the first level device of a nested clock distribution tree. In these two situations the only parameter of importance will be the relative position of each output with respect to the other outputs on that die. Since these outputs will all see the same environmental and process conditions the skew will be significantly less than the propagation delay windows specified in the standard device data sheet.

Figure 2. Output-to-Output Skew

## Part-to-Part Skew

The part-to-part skew specification is by far the most difficult performance aspect of a device to minimize. Because the part-to-part skew is dependent on both process variations and variations in the environment the resultant specification is significantly larger than for the other two components of skew. Many times a vendor will provide subsets of part-to-part skew specifications based on non-varying environmental conditions. Care should be taken in reading data sheets to fully understand the conditions under which the specified limits are guaranteed. If the part-to-part skew is specified and is different than the specified propagation delay window for the device one can be assured there are constraints on the part-to-part skew specification.

Power supply and temperature variations are major contributors to variations in propagation delays of silicon devices. Constraints on these two parameters are commonly seen in part-to-part skew specifications. Although there are situations where the power supply variations could be ignored, it is difficult for this author to perceive of a realistic system whose devices are all under identical thermal conditions. Hot spots on boards or cabinets, interruption in air flow and variations in IC density of a board all lead to thermal gradients within a system. These thermal gradients will guarantee that devices in various parts of the system are under different junction temperature conditions. Although it is unlikely that a
designer will need the entire commercial temperature range, a portion of this range will need to be considered. Therefore, a part-to-part skew specified for a single temperature is of little use, especially if the temperature coefficient of the propagation delay is relatively large.

For designs whose clock distribution networks lie on a single board which utilizes power and ground planes an assumption of non-varying power supplies would be a valid assumption and a specification limit for a single power supply would be valuable. If, however, various pieces of the total distribution tree will be on different boards within a system there is a very real possibility that each device will see different power supply levels. In this case a specification limit for a fixed $\mathrm{V}_{\mathrm{CC}}$ will be inadequate for the design of the system. Ideally the data sheets for clock distribution devices should include information which will allow designers to tailor the skew specifications of the device to their application environment.

## SYSTEM ADVANTAGES OF ECL

## Skew Reductions

ECL devices provide superior performance in all three areas of skew over their TTL or CMOS competitors. A skew reducing mechanism common to all skew parameters is the faster propagation delays of ECL devices. Since, to some extent, all skew represent a percentage of the typical delays faster delays will usually mean smaller skews. ECL devices, especially clock distribution devices, can be operated in either single-ended or differential modes. To minimize the skew of these devices the differential mode of operation should be used, however even in the single-ended mode the skew performance will be significantly better than for CMOS or TTL drivers.

Figure 3. VBB Induced Duty Cycle Skew
ECL output buffers inherently show very little difference between TPLH and TPHL delays. What differences one does see are due mainly to switching reference levels which are not ideally centered in the input swing (see Figure 3). For worst case switching reference levels the pulse skew of an ECL device will still be less than 300ps. If the ECL device is used differentially the variation in the switching reference will not impact the duty cycle skew as it is not used. In this case the pulse skew will be less than 50ps and can generally be ignored in all but the highest performance designs. The problem of generating clocks which are capable of meeting the duty cycle requirements of the most advanced microprocessors, would be a trivial task if differential ECL compatible clock inputs were used. TTL and CMOS clock drivers on the other hand have
inherent differences between the TPLH and TPHL delays in addition to the problems with non-centered switching thresholds. In devices specifically designed to minimize this parameter it generally cannot be guaranteed to anything less than 1 ns .

The major contributors to output-to-output skew is IC layout and package choice. Differences in internal paths and paths through the package generally can be minimized regardless of the silicon technology utilized at the die level, therefore ECL devices offer less of an advantage in this area than for other skew parameters. CMOS and TTL output performance is tied closely to the power supply levels and the stability of the power busses within the chip. Clock distribution trees by definition always switch simultaneously, thus creating significant disturbances on the internal power busses. To alleviate this problem multiple power and ground pins are utilized on TTL and CMOS clock distribution devices. However even with this strategy TTL and CMOS clock distribution devices are limited to 500 ps -700 ps output-to-output skew guarantees. With differential ECL outputs very little if any noise is generated and coupled onto the internal power supplies. This coupled with the faster propagation delays of the output buffers produces output-to-output skews on ECL clock chips as low as 50ps.
Two aspects of ECL clock devices will lead to significantly smaller part-to-part skews than their CMOS and TTL competitors: faster propagation delays and delay insensitivity to environmental variations. Variations in propagation delays with process are typically going to be based on a percentage of the typical delay of the device. Assuming this percentage is going to be approximately equivalent between ECL, TTL and CMOS processes, the faster the device the smaller the delay variations. Because state-of-the-art ECL devices are at least 5 times faster than TTL and CMOS devices, the expected delay variation would be one fifth those of CMOS and TTL devices without even considering environmental dependencies.

The propagation delays of an ECL device are insensitive to variations in power supply while CMOS and TTL device propagation delays vary significantly with changes in this parameter. Across temperature the percentage variation for all technologies is comparable, however, again the faster propagation delays of ECL will reduce the magnitude of the variation. Figure 4 on the following page represents normalized propagation delay versus temperature and power supply for the three technologies.

## Low Impedance Line Driving

The clock requirements of today's systems necessitate an almost exclusive use of controlled impedance interconnect. In the past this requirement was unique to the performance levels associated with ECL technologies, and in fact precluded its use in all but the highest performance systems. However the high performance CMOS and TTL clock distribution chips now require care in the design and layout of PC boards to optimize their performance, with this criteria established the migration from these technologies to ECL is simplified. In fact, the difficulties involved in designing with these "slower" technologies in a controlled impedance environment may even enhance the potential of using ECL devices as they are ideally suited to the task.

Figure 4. TPD vs Environmental Condition Comparison

The low impedance outputs and high impedance inputs of an ECL device are ideal for driving $50 \Omega$ to $130 \Omega$ controlled impedance transmission lines. The specified driving impedance of ECL is $50 \Omega$, however this value is used only for convenience sake due to the $50 \Omega$ impedance of most commonly used measurement equipment. Utilizing higher impedance lines will reduce the power dissipated by the termination resistors and thus should be considered in power sensitive designs. The major drawback of higher impedance lines (delays more dependent on capacitive loading) may not be an issue in the point to point interconnect scheme generally used in low skew clock distribution designs.

## Differential Interconnect

The device skew minimization aspects of differential ECL have already been discussed however there are other system level advantages that should be mentioned. Whenever clock lines are distributed over long distances the losses in the line and the variations in power supply upset the ideal relationship between input voltages and switching thresholds. Because differential interconnect "carries" the switching threshold information from the source to the load the relationship between the two is less likely to be changed. In addition for long lines the smaller swings of an ECL device produce much lower levels of cross-talk between adjacent lines and minimizes EMI radiation from the PC board.
There is a cost associated with fully differential ECL, more pins for equivalent functions and more interconnect to be laid on a typically already crowded PC board. The first issue is really a non-issue for clock distribution devices. The output-to-output and duty cycle skew are very much dependent on quiet internal power supplies. Therefore the pins sacrificed for the complimentary outputs would otherwise have to be used as power supply pins, thus functionality is actually gained for an equivalent pin count as the inversion function is also available on a differential device. The presence of the inverted signal could be invaluable for a design which clocks both off the positive and negative edges. Figure 5 shows a method of obtaining very low skew (<50ps)
$180^{\circ}$ shifted two phase clocks.
It is true that differential interconnect requires more signals to be routed on the PC board. Fortunately with the wide data and address buses of today's designs the clock lines represent a small fraction of the total interconnect. The final choice as to whether or not to use differential interconnect lies in the level of skew performance necessary for the design. It should be noted that although single-ended ECL provides less attractive skew performance than differential ECL, it does provide significantly better performance than equivalent CMOS and TTL functions.

Figure 5. $180^{\circ}$ Shifted Two Phase Clocks

## USING ECL WITH POSITIVE SUPPLIES

It is hard to argue with the clock distribution advantages of ECL presented thus far, but it may be argued that except for all ECL designs it is too costly to include ECL devices in the distribution tree. This claim is based on the assumption that at least two extra power supplies are required; the negative $\mathrm{V}_{\mathrm{EE}}$ supply and the negative $\mathrm{V}_{\mathrm{T} T}$ termination voltage. Fortunately both these assumptions are false. PECL (Positive ECL) is an acronym which describes using ECL devices with a positive
rather than negative power supply. It is important to understand that all ECL devices are also PECL devices. By using ECL devices as PECL devices on a +5 volt supply and incorporating termination techniques which do not require a separate termination voltage (series termination, thevenin equivalent) ECL can be incorporated in a CMOS or TTL design with no added cost.
The reason for the choice of negative power supplies as standard for ECL is due to the fact that all of the output levels and internal switching bias levels are referenced to the $\mathrm{V}_{\mathrm{CC}}$ rail. It is generally easier to keep the grounds quieter and equal potential throughout a system than it is with a power supply. Because the DC parameters are referenced to the $\mathrm{V}_{\mathrm{CC}}$ rail any disturbances or voltage drops seen on $\mathrm{V}_{\mathrm{CC}}$ will translate 1:1 to the output and internal reference levels. For this reason when communicating with PECL between two boards it is recommended that only differential interconnect be used. By using differential interconnect $\mathrm{V}_{\mathrm{CC}}$ variations within the specified range will not in any way affect the performance of the device.
Finally mentioning ECL to a CMOS designer invariably conjures up visions of space heaters as their perception of ECL is high power. Although it is true that the static power of ECL is higher than for CMOS the dynamic power differences between the technologies narrows as the frequency increases. As can be seen in Figure 6 at frequencies as low as 20 MHz the per gate power of ECL is actually less than for CMOS. Since clock distribution devices are never static it does not make sense to compare the power dissipation of the two technologies in a static environment.

Figure 6. ICC/Gate vs Frequency Comparison

## MIXED SIGNAL CLOCK DISTRIBUTION

## ECL Clock Distribution Networks

Clock distribution in a ECL system is a relatively trivial matter. Figure 7 illustrates a two level clock distribution tree which produces nine differential ECL clocks on six different cards. The ECLinPS E211 device gives the flexibility of disabling each of the cards individually. In addition the
synchronous registered enables will disable the device only when the clock is already in the LOW state, thus avoiding the problem of generating runt pulses when an asynchronous disable is used. The device also provides a muxed clock input for incorporating a high speed system clock and a lower speed test or scan clock within the same distribution tree. The ECLinPS E111 device is used to receive the signals from the backplane and distribute it on the card. The worst case skew between all 54 clocks in this situation would be 275ps assuming that all the loads and signal traces are equalized.

Figure 7. ECL Clock Distribution Tree

## Mixed Technology Distribution Networks

Building clock networks in TTL and CMOS systems can be a little more complicated as there are more alternatives available. For simple one level distribution trees fanout devices like the MECL 10H645 1:9 TTL to TTL fanout tree can be used. However as the number of levels of fanout increases the addition of ECL devices in an other wise TTL or CMOS system becomes attractive. In Figure 8 on the next page an E111 device is combined with a MECL H641 device to produce 81 TTL level clocks. Analyzing the skew between the 81 clocks yields a worst case skew, allowing for the full temperature and $\mathrm{V}_{\mathrm{CC}}$ range variation, of 1.25 ns . Under ideal situations, no variation in temperature or VCC supply, the skew would be only 750 ps. When compared with distribution trees utilizing only TTL or CMOS technologies these numbers represent $\approx 50 \%$ improvement, more if the environmental conditions vary to any degree. For a 50 MHz clock the total skew between the 81 TTL clocks is less than $6.5 \%$ of the clock period, thus providing the designer extra margin for layout induced skew to meet the overall skew budget of the design.

Many designers have already realized the benefits of ECL clock distribution trees and thus are implementing them in their designs. Furthermore where they have the capability, i.e. ASICs, they are building their VLSI circuits with ECL compatible clock inputs. Unfortunately other standard VLSI circuits such as microprocessors, microprocessor support chips and memory still cling to TTL or CMOS clock inputs. As a result many systems need both ECL and TTL clocks within the same system. Unlike the situation outlined in Figure 8 the ECL levels are not merely intermediate signals but rather are
driving the clock inputs of the logic. As a result the ECL edges need to be matched with the TTL edges as pictured in Figure 9.

Figure 8. ECL to TTL Clock Distribution

Figure 9. Mixed ECL and TTL Distribution
An ECL clock driver will be significantly faster than a TTL or CMOS equivalent function. Therefore to de-skew the ECL and TTL signals of Figure 9 a delay needs to be added to the input of the ECL device. Because a dynamic delay adjust would not lend itself to most production machines a static delay would be
used. The value of the delay element would be a best guess estimate of the differences in the two propagation delays. It is highly unlikely that the temperature coefficients of the propagation delays of the ECL devices, TTL devices and delay devices would be equal. Although these problems will add skew to the system, the resultant total skew of the distribution network will be less than if no ECL chips were used.

## PLL Based Clock Drivers

A potential solution for the problem outlined in Figure 9 is in the use of phase locked loop based clock distribution chips. Because these devices feedback an output and lock it to a reference clock input the delay differences between the various technology output buffers will be eliminated. One might believe that with all of the euphoria surrounding the performance of PLL based clock distribution devices that the need for any ECL in the distribution tree will be eliminated. However when analyzed further the opposite appears to be the case.

For a single board design with a one level distribution system there obviously is no need for ECL. When, however, a multiple board system is required where nested levels of devices are needed ECL once again becomes useful. One major aspect of part-to-part skew for PLL based clock chips often overlooked is the dependence on the skew of the various reference clocks being locked to. As can be seen in Figure 10 the specified part-to-part skew of the device would necessarily need to be added to the reference clock skew to get the overall skew of the clock tree. From the arguments presented earlier this skew will be minimized if the reference clock is distributed in ECL. It has not been shown as of yet where a PLL based ECL clock distribution chip can provide the skew performance of the simple fanout buffer. From a system standpoint the buffer type circuits are much easier to design with and thus given equivalent performance would represent the best alternative. The extra features provided by PLL based chips could all be realized if they were used in only the final stage of the distribution tree.

The MPC973 is a PLL based clock driver which features differential PECL reference clock inputs. When combined with the very low skew MC10E111 fanout buffer, very low skew clock trees can be realized for multiprocessor MPP designs. There will be a family of devices featuring various technology compatible inputs and outputs to allow for the building of precisely aligned clock trees based on either ECL, TTL, CMOS or differential GTL (or a mixture of all four) compatible levels.

Figure 10. System Skew For PLL Clock Distribution

## Conclusion

The best way to maximize the performance of any synchronous system is to spend the entire clock period performing value added operations. Obviously any portion of the clock period spent idle due to clock skew limits the potential performance of the system. Using ECL technology devices in clock distribution networks will minimize all aspects of skew and thus maximize the performance of a system. Unfortunately the VLSI world is not yet ECL clock based so that the benefits of a totally ECL based distribution tree cannot be realized for many systems. However there are methods of incorporating ECL into the intermediate levels of the tree to significantly reduce the overall skew. In addition the system designers can utilize their new found knowledge to incorporate ECL compatible clocks on those VLSI chips of which they have control while at the same time pressuring other VLSI vendors in doing the same so that future designs can enjoy fully the advantages of distributing clocks with ECL.

Prepared by
Cleon Petty
Todd Pearson
ECL Applications Engineering

This application note provides detailed information on designing with Positive Emitter Coupled Logic (PECL) devices.

MOTOROLA

# Designing With PECL (ECL at +5.0V) The High Speed Solution for the CMOS/TTL Designer 

## Introduction

PECL, or Positive Emitter Coupled Logic, is nothing more than standard ECL devices run off of a positive power supply. Because ECL, and therefore PECL, has long been the "black magic" of the logic world many misconceptions and falsehoods have arisen concerning its use. However, many system problems which are difficult to address with TTL or CMOS technologies are ideally suited to the strengths of ECL. By breaking through the wall of misinformation concerning the use of ECL, the TTL and CMOS designers can arm themselves with a powerful weapon to attack the most difficult of high speed problems.

It has long been accepted that ECL devices provide the ultimate in logic speed; it is equally well known that the price for this speed is a greater need for attention to detail in the design and layout of the system PC boards. Because this requirement stems only from the speed performance aspect of ECL devices, as the speed performance of any logic technology increases these same requirements will hold. As can be seen in Table 1 the current state-of-the-art TTL and CMOS logic families have attained performance levels which require controlled impedance interconnect for even relatively short distances between source and load. As a result system designers who are using state-of-the-art TTL or CMOS logic are already forced to deal with the special requirements of high speed logic; thus it is a relatively small step to extend their thinking from a TTL and CMOS bias to include ECL devices where their special characteristics will simplify the design task.

Table 1. Relative Logic Speeds

| Logic <br> Family | Typical Output <br> Rise/Fall | Maximum Open Line <br> Length $\left(L_{m a x}\right)^{*}$ |
| :---: | :---: | :---: |
| 10 KH | 1.0 ns | $3^{\prime \prime}$ |
| ECLinPS | 400 ps | $1^{\prime \prime}$ |
| FAST | 2.0 ns | $6^{\prime \prime}$ |
| FACT | 1.5 ns | $4^{\prime \prime}$ |

* Approximate for stripline interconnect ( $\mathrm{L}_{\mathrm{max}}=\mathrm{T}_{\mathrm{r}} / 2 \mathrm{~T}_{\mathrm{pd}}$ )

## System Advantages of ECL

The most obvious area to incorporate ECL into an otherwise CMOS/TTL design would be for a subsystem which requires very fast data or signal processing. Although this is the most obvious it may also be the least common. Because of the need for translation between ECL and CMOS/TTL technologies the performance gain must be greater than the overhead required to translate back and forth between technologies. With typical delays of six to seven nanoseconds
for translating between technologies, a significant portion of the logic would need to be realized using ECL for the overall system performance to improve. However, for very high speed subsystem requirements ECL may very well provide the best system solution.

## Transmission Line Driving

Many of the inherent features of an ECL device make it ideal for driving long, controlled impedance lines. The low impedance of the open emitter outputs and high input impedance of any standard ECL device make it ideally suited for driving controlled impedance lines. Although designed to drive $50 \Omega$ lines an ECL device is equally adept at driving lines of impedances of up to $130 \Omega$ without significant changes in the AC characteristics of the device. Although some of the newer CMOS/TTL families have the ability to drive $50 \Omega$ lines many require special driver circuits to supply the necessary currents to drive low impedance transmission interconnect. In addition the large output swings and relatively fast output slew rates of today's high performance CMOS/TTL devices exacerbate the problems of crosstalk and EMI radiation. The problems of crosstalk and EMI radiation, along with common mode noise and signal amplitude losses, can be alleviated to a great degree with the use of differential interconnect. Because of their architectures, neither CMOS nor TTL devices are capable of differential communication. The differential amplifier input structure and complimentary outputs of ECL devices make them perfectly suited for differential applications. As a result, for systems requiring signal transmission between several boards, across relatively large distances, ECL devices provide the CMOS/TTL designer a means of ensuring reliable transmission while minimizing EMI radiation and crosstalk.

Figure 1 shows a typical application in which the long line driving, high bandwidth capabilities of ECL can be utilized. The majority of the data processing is done on wide bit width words with a clock cycle commensurate with the bandwidth capabilities of CMOS and TTL logic. The parallel data is then serialized into a high bandwidth data stream, a bandwidth which requires ECL technologies, for transmission across a long line to another box or machine. The signal is received differentially and converted back to relatively low speed parallel data where it can be processed further in CMOS/TTL logic. By taking advantage of the bandwidth and line driving capabilities of ECL the system minimizes the number of lines required for interconnecting the subsystems without sacrificing the overall performance. Furthermore by taking advantage of PECL this application can be realized with a single five volt power supply. The configuration of Figure 1 illustrates a situation where the mixing of logic technologies can produce a design which maximizes the overall performance while managing power dissipation and minimizing cost.

AN1406

Figure 1. Typical Use of ECL's High Bandwidth, Line Driving Capabilities

## Clock Distribution

Perhaps the most attractive area for ECL in CMOS/ TTL designs is in clock distribution. The ever increasing performance capabilities of today's designs has placed an even greater emphasis on the design of low skew clock generation and distribution networks. Clock skew, the difference in time between "simultaneous" clock transitions throughout an entire system, is a major component of the constraints which form the upper bound for the system clock frequency. Reductions in system clock skew allow designers to increase the performance of their designs without having to resort to more complicated architectures or costly, faster logic. ECL logic has the capability of significantly reducing the clock skew of a system over an equivalent design utilizing CMOS or TTL technologies.
The skew introduced by a logic device can be broken up into three areas; the part-to-part skew, the within-part skew and the rise-to-fall skew. The part-to-part skew is defined as the differences in propagation delays between any two devices while the within-device skew is the difference between the propagation delays of similar paths for a single device. The final portion of the device skew is the rise-to-fall skew or simply the differences in propagation delay between a rising input and a failing input on the same gate. The within-device skew and the rise-to-fall skew combine with delay variations due to environmental conditions and processing to comprise the part-to-part skew. The part-to-part skew is defined by the propagation delay window described in the device data sheets.

Careful attention to die layout and package choice will minimize within-device skew. Although this minimization is independent of technology, there are other characteristics of ECL which will further reduce the skew of a device. Unlike their CMOS/TTL counterparts, ECL devices are relatively insensitive to variations in supply voltage and temperature.

Propagation delay variations with environmental conditions must be accounted for in the specification windows of a device. As a result because of ECLs AC stability the delay windows for a device will inherently be smaller than similar CMOS or TTL functions.
The virtues of differential interconnect in line driving have already been addressed, however the benefits of differential interconnect are even more pronounced in clock distribution. The propagation delay of a signal through a device is intimately tied to the switching threshold of that device. Any deviations of the threshold from the center of the input voltage swing will increase or decrease the delay of the signal through the device. This difference will manifest itself as rise-to-fall skew in the device. The threshold levels for both CMOS and TTL devices are a function of processing, layout, temperature and other factors which are beyond the control of the system level designer. Because of the variability of these switching references, specification limits must be relaxed to guarantee acceptable manufacturing yields. The level of relaxation of these specifications increases with increasing logic depth. As the depth of the logic within a device increases the input signal will switch against an increasing number of reference levels; each encounter will add skew when the reference level is not perfectly centered. These relaxed timing windows add directly to the overall system skew. Differential ECL, both internal and external to the die, alleviates this threshold sensitivity as a DC switching reference is no longer required. Without the need for a switching reference the delay windows, and thus system skew, can be significantly reduced while maintaining acceptable manufacturing yields.

What does this mean to the CMOS/TTL designer? It means that CMOS/TTL designers can build their clock generation card and backplane clock distribution using ECL. Designers will not only realize the benefits of driving long lines with ECL but will also be able to realize clock distribution networks with skew specs unheard of in the CMOS/TTL world. Many
specialized functions for clock distribution are available from Motorola (MC10/100E111, MC10/100E211, MC10/100EL11). Care must be taken that all of the skew gained using ECL for clock distribution is not lost in the process of translating into CMOS/TTL levels. To alleviate this problem the MC10/100H646 can be used to translate and fanout a differential ECL input signal into TTL levels. In this way all of the fanout on the backplane can be done in ECL while the fanout on each card can be done in the CMOS/TTL levels necessary to drive the logic.

Figure 2 illustrates the use of specialized fanout buffers to design a CMOS/TTL clock distribution network with minimal skew. With 50ps output-to-output skew of the MC10/100E111 and 1 ns part-to-part skew available on the MC10/100H646 or MC10/100H641, a total of 72 or 81 TTL clocks, respectively, can be generated with a worst case skew between all outputs of only 1.05 ns . A similar distribution tree using octal CMOS or TTL buffers would result in worst case skews of more than 6 ns . This 5 ns improvement in skew equates to about $50 \%$ of the up/down time of a 50 MHz clock cycle. It is not difficult to imagine situations where an extra $50 \%$ of time to perform necessary operations would be either beneficial or even a life saver. For more information about using ECL for clock distribution, refer to application note AN1405/D - ECL Clock Distribution Techniques.

Figure 2. Low Skew Clock Fanout Tree

## PECL versus ECL

Nobody will argue that the benefits presented thus far are not attractive, however the argument will be made that the benefits are not enough to justify the requirements of including ECL devices in a predominantly CMOS/TTL design. After all the inclusion of ECL requires two additional negative voltage supplies; $\mathrm{V}_{\text {EE }}$ and the terminating voltage $\mathrm{V}_{\mathrm{TT}}$. Fortunately this is where the advantages of PECL come into play. By using ECL devices on a positive five volt CMOS/TTL power supply and using specialized termination techniques ECL logic can be incorporated into CMOS/TTL designs without the need for additional power supplies. What about power dissipation you
ask, although it is true that in a DC state ECL will typically dissipate more power than a CMOS/TTL counterpart, in applications which operate continually at frequency, i.e.. clock distribution, the disparity between ECL and CMOS/TTL power dissipation is reduced. The power dissipation of an ECL device remains constant with frequency while the power of a CMOS/TTL device will increase with frequency. As frequencies approach 50 MHz the difference between the power dissipation of a CMOS or TTL gate and an ECL gate will be minimal. 50 MHz clock speeds are becoming fairly common in CMOS/TTL based designs as today's high performance MPUs are fast approaching these speeds. In addition, because ECL output swings are significantly less than those of CMOS and TTL the power dissipated in the load will be significantly less under continuous AC conditions.

It is clear that PECL can be a powerful design tool for CMOS/TTL designers, but where can one get these PECL devices. Perhaps the most confusing aspect of PECL is the misconception that a PECL device is a special adaptation of an ECL device. In reality every ECL device is also a PECL device; there is nothing magical about the negative voltage supply used for ECL devices. The only real requirement of the power supplies is that the potential difference described in the device data sheets appears across the upper and lower power supply rails ( $\mathrm{V}_{\mathrm{CC}}$ and $\mathrm{V}_{\mathrm{EE}}$ respectively). A potential stumbling block arises in the specified $V_{E E}$ levels for the various ECL families. The 10 H and 100 K families specify parametric values for potential differences between $\mathrm{V}_{\mathrm{CC}}$ and $\mathrm{V}_{\mathrm{EE}}$ of 4.94 V to 5.46 V and 4.2 V to 4.8 V respectively; this poses a problem for the CMOS/TTL designer who works with a typical $\mathrm{V}_{\mathrm{CC}}$ of 5.0 V $\pm 5 \%$. However, because both of these ECL standards are voltage compensated both families will operate perfectly fine and meet all of the performance specifications when operated on standard CMOS/TTL power supplies. In fact, Motorola is extending the $\mathrm{V}_{\mathrm{EE}}$ specification ranges of many of their ECL families to be compatible with standard CMOS/TTL power supplies. Unfortunately earlier ECL families such as MECL $10 \mathrm{~K}^{\text {TM }}$ are not voltage compensated and therefore any reduction in the potential difference between the two supplies will result in an increase in the $\mathrm{V}_{\text {OL }}$ level, and thus a decreased noise margin. For the typical CMOS/TTL power supplies a 10 K device will experience an $\approx 50 \mathrm{mV}$ increase in the $\mathrm{V}_{\mathrm{OL}}$ level. Designers should analyze whether this loss of noise margin could jeopardize their designs before implementing PECL formatted 10 K using $5.0 \mathrm{~V} \pm 5 \%$ power supplies.

The traditional choice of a negative power supply for ECL is the result of the upper supply rail being used as the reference for the I/0 and internal switching bias levels of the technology. Since these critical parameters are referenced to the upper rail any noise on this rail will couple 1:1 onto them; the result will be reduced noise margins in the design. Because, in general, it is a simpler task to keep a ground rail relatively noise free, it is beneficial to use the ground rail as this reference. However when careful attention is paid to the power supply design, PECL can be used to optimize system performance. Once again the use of differential PECL will simplify the designer's task as the noise margins of the system will be doubled and any noise riding on the upper $\mathrm{V}_{\mathrm{CC}}$ rail will appear as common mode noise; common mode noise will be rejected by the differential receiver.

## MECL to PECL DC Level Conversion

Although using ECL on positive power supplies is feasible, as with any high speed design there are areas in which special attention should be placed. When using ECL devices with positive supplies the input output voltage levels need to be translated. This translation is a relatively simple task. Since these levels are referenced off of the most positive rail, $\mathrm{V}_{\mathrm{CC}}$, the following equation can be used to calculate the various specified DC levels for a PECL device:
PECL Level = VCCNEW - |Specification Level|

As an example, the $\mathrm{V}_{\text {OHMAX }}$ level for a 10 H device operating with a $\mathrm{V}_{\mathrm{CC}}$ of 5.0 V at $25^{\circ} \mathrm{C}$ would be as follows:

$$
\begin{aligned}
& \text { PECL Level }=5.0 \mathrm{~V}-|-0.81 \mathrm{~V}| \\
& \text { PECL Level }=(5.0-0.81) \mathrm{V}=4.19 \mathrm{~V}
\end{aligned}
$$

The same procedure can be followed to calculate all of the DC levels, including $\mathrm{V}_{\mathrm{BB}}$ for any ECL device. Table 2 at the bottom of the page outlines the various PECL levels for a $\mathrm{V}_{\mathrm{CC}}$ of 5.0 V for both the 10 H and 100K ECL standards. As mentioned earlier any changes in $V_{C C}$ will show up 1:1 on the output DC levels. Therefore any tolerance values for $\mathrm{V}_{\mathrm{CC}}$ can be transferred to the device I/O levels by simply adding or subtracting the $\mathrm{V}_{\mathrm{CC}}$ tolerance values from those values provided in Table 2.

## PECL Termination Schemes

PECL outputs can be terminated in all of the same ways standard ECL, this would be expected since an ECL and a PECL device are one in the same. Figure 3 illustrates the various output termination schemes utilized in typical ECL systems. For best performance the open line technique in Figure 3 would not be used except for very short interconnect between devices; the definition of short can be found in the various design guides for the different ECL families. In general for the fastest performance and the ability to drive distributive loads the parallel termination techniques are the best choice. However occasions may arise where a long uncontrolled or variable impedance line may need to be driven; in this case the series termination technique would be appropriate. For a more
thorough discourse on when and where to use the various termination techniques the reader is referred to the MECL System Design Handbook (HB205/D) and the design guide in the ECLinPS Databook (DL140/D). The parallel termination scheme of Figure 3 requires an extra $\mathrm{V}_{\mathrm{TT}}$ power supply for the impedance matching load resistor. In a system which is built mainly in CMOS/TTL this extra power supply requirement may prohibit the use of this technique. The other schemes of Figure 3 use only the existing positive supply and ground and thus may be more attractive for the CMOS/ TTL based machine.

## Parallel Termination Schemes

Because the techniques using an extra $\mathrm{V}_{\mathrm{TT}}$ power supply consume significantly less power, as the number of PECL devices incorporated in the design increases the more attractive the $\mathrm{V}_{\mathrm{T}}$ supply termination scheme becomes. Typically ECL is specified driving $50 \Omega$ into a -2.0 V , therefore for PECL with a $\mathrm{V}_{\mathrm{CC}}$ supply different than ground the $\mathrm{V}_{\mathrm{TT}}$ terminating voltage will be $\mathrm{V}_{\mathrm{CC}}-2.0 \mathrm{~V}$. Ideally the $\mathrm{V}_{\mathrm{TT}}$ supply would track $1: 1$ with $\mathrm{V}_{\mathrm{CC}}$, however in theory this scenario is highly unlikely. To ensure proper operation of a PECL device within the system the tolerances of the $\mathrm{V}_{\mathrm{TT}}$ and the $\mathrm{V}_{\mathrm{CC}}$ supplies should be considered. Assume for instance that the nominal case is for a $50 \Omega$ load $\left(R_{t}\right)$ into a +3.0 V supply; for a 10 H compatible device with a $\mathrm{V}_{\mathrm{OH} \max }$ of -0.81 V and a realistic $V_{\text {OLmin }}$ of -1.85 V the following can be derived:

$$
\begin{aligned}
& \mathrm{IOHmax}=\left(\mathrm{V}_{\mathrm{OH}} \max -\mathrm{V}_{\mathrm{TT}}\right) / \mathrm{R}_{\mathrm{t}} \\
& \mathrm{I}_{\mathrm{OH} \max }=(\{5.0-0.81\}-3.0) / 50=23.8 \mathrm{~mA} \\
& \mathrm{I}_{\mathrm{OLmin}}=\left(\mathrm{V}_{\mathrm{OLmin}}-\mathrm{V}_{\mathrm{TT}}\right) / R_{\mathrm{t}} \\
& \mathrm{I}_{\mathrm{OLmin}}=(\{5.0-0.81\}-3.0) / 50=3.0 \mathrm{~mA}
\end{aligned}
$$

If $+5 \%$ supplies are assumeda $\mathrm{V}_{\mathrm{CC}}$ of $\mathrm{V}_{\mathrm{CCnom}}-5 \%$ anda $\mathrm{V}_{\mathrm{TT}}$ of $\mathrm{V}_{\mathrm{TTnom}}+5 \%$ will represent the worst case. Under these conditions, the following output currents will result:

$$
\begin{aligned}
& \mathrm{I} \mathrm{OHmax}=(\{4.75-0.81\}-3.15) / 50=15.8 \mathrm{~mA} \\
& \mathrm{IOLmin}=(\{4.75-1.85\}-3.15) / 50=0 \mathrm{~mA}
\end{aligned}
$$

Using the other extremes for the supply voltages yields:

$$
\begin{aligned}
& \mathrm{IOHmax}=31.8 \mathrm{~mA} \\
& \text { IOLmin }=11 \mathrm{~mA}
\end{aligned}
$$

Table 2. ECL/PECL DC Level Conversion for VCC $=5.0 \mathrm{~V}$

## Figure 3. Termination Techniques for ECL/PECL Devices

The changes in the $\mathrm{I}_{\mathrm{OH}}$ currents will affect the $\mathrm{DC} \mathrm{V}_{\mathrm{OH}}$ levels by $\approx \pm 40 \mathrm{mV}$ at the two extremes. However in the vast majority of cases the DC levels for ECL devices are well centered in their specification windows, thus this variation will simply move the level within the valid specification window and no loss of worst case noise margin will be seen. The IOL situation on the other hand does pose a potential AC problem. In the worst case situation the output emitter follower could move into the cutoff state. The output emitter followers of ECL devices are designed to be in the conducting "on" state at all times. If cutoff, the delay of the device will be increased due to the extra time required to pull the output emitter follower out of the cutoff state. Again this situation will arise only under a number of simultaneous worst case situations and therefore is highly unlikely to occur, but because of the potential it should not be overlooked.

## Thevenin Equivalent Termination Schemes

The Thevenin equivalent parallel termination technique of Figure 3 is likely the most attractive scheme for the CMOS/TTL designer who is using a small amount of ECL. As mentioned earlier this technique will consume more power, however the absence of an additional power supply will more than compensate for the extra power consumption. In addition, this extra power is consumed entirely in the external resistors and thus will not affect the reliability of the IC. As is the case with standard parallel termination, the tolerances of the $\mathrm{V}_{\mathrm{T}}$ and $\mathrm{V}_{\mathrm{CC}}$ supplies should be addressed in the design phase. The following equations provide a means of determining the two resistor values and the resulting equivalent $\mathrm{V}_{\mathrm{T} T}$ terminating voltage.

$$
\begin{aligned}
& \mathrm{R} 1=\mathrm{R} 2\left(\left\{\mathrm{~V}_{C C}-\mathrm{V}_{\mathrm{T} T}\right\} /\left\{\mathrm{V}_{T T}-\mathrm{V}_{E E}\right\}\right. \\
& \mathrm{R} 2=\mathrm{Z}_{\mathrm{O}}\left(\left\{\mathrm{~V}_{\mathrm{CC}}-\mathrm{V}_{E E}\right\} /\left\{\mathrm{V}_{\mathrm{CC}}-\mathrm{V}_{\mathrm{TT}}\right\}\right) \\
& \mathrm{V}_{\mathrm{TT}}=\mathrm{V}_{\mathrm{CC}}(\mathrm{R} 2 /\{\mathrm{R} 1+\mathrm{R} 2\})
\end{aligned}
$$

For the typical setup:

$$
\begin{aligned}
& \mathrm{V}_{\mathrm{CC}}=5.0 \mathrm{~V} ; \mathrm{V}_{\mathrm{EE}}=\mathrm{GND} ; \mathrm{V}_{\mathrm{TT}}=3.0 \mathrm{~V} ; \text { and } \mathrm{Z}_{\mathrm{O}}=50 \Omega \\
& \mathrm{R} 2=50(\{5-0\} /\{5-3\})=125 \Omega \\
& \mathrm{R} 1=125(\{5-3\} /\{3-0\})=83.3 \Omega
\end{aligned}
$$

checking for $\mathrm{V}_{\mathrm{TT}}$

$$
\mathrm{V}_{\mathrm{TT}}=5(125 /\{125-83.3\})=3.0 \mathrm{~V}
$$

Because of the resistor divider network used to generate $\mathrm{V}_{\mathrm{TT}}$ the variation in V will be intimately tied to the variation in $\mathrm{V}_{\mathrm{CC}}$. Differentiating the equation for $\mathrm{V}_{\mathrm{T} T}$ with respect to $\mathrm{V}_{\mathrm{CC}}$ yields:

$$
\mathrm{d} \mathrm{~V}_{\mathrm{TT}} / \mathrm{d} \mathrm{~V}_{\mathrm{CC}}=\mathrm{R} 2 /(\mathrm{R} 1+\mathrm{R} 2) \mathrm{d} \mathrm{~V}_{\mathrm{CC}}
$$

Again for the nominal case this equation reduces to:

$$
\Delta \mathrm{V}_{\mathrm{TT}}=0.6 \Delta \mathrm{~V}_{\mathrm{CC}}
$$

So that for $\Delta \mathrm{V}_{\mathrm{CC}}= \pm 5 \%= \pm 0.25 \mathrm{~V}, \Delta \mathrm{~V}_{\mathrm{TT}}= \pm 0.15 \mathrm{~V}$.
As mentioned previously the real potential for problems will be if the VOL level can potentially put the output emitter follower into cutoff. Because of the relationship between the $\mathrm{V}_{\mathrm{CC}}$ and $\mathrm{V}_{\mathrm{T}}$ levels the only situation which could present a problem will be for the lowest value of $\mathrm{V}_{\mathrm{CC}}$. Applying the equation for IOLmin under this condition yields:

$$
\begin{aligned}
& \text { IOLmin }=\left(\left\{\mathrm{V}_{\mathrm{OL}} \min -\mathrm{V}_{\mathrm{TT}}\right\} / \mathrm{R}_{\mathrm{t}}\right. \\
& \text { IOLmin }=(\{4.75-1.85\}-2.85) / 50=1.0 \mathrm{~mA}
\end{aligned}
$$

From this analysis it appears that there is no potential for the output emitter follower to be cutoff. This would suggest that the Thevenin equivalent termination scheme is actually a better design to compensate for changes in $\mathrm{V}_{\mathrm{CC}}$ due to the fact that these changes will affect $\mathrm{V}_{\mathrm{T}}$, although not $1: 1$ as would be ideal, in the same way. To make the design even more immune to potential output emitter follower cutoff the designer can design for nominal operation for the worst case situation. Since the designer has the flexibility of choosing the $\mathrm{V}_{\mathrm{T}}$ level via the selection of the R1 and R2 resistors the following procedure can be followed.

Let $\mathrm{V}_{\mathrm{CC}}=4.75 \mathrm{~V}$ and $\mathrm{V}_{\mathrm{TT}}=\mathrm{V}_{\mathrm{CC}}-2.0 \mathrm{~V}=2.75 \mathrm{~V}$ Therefore:

$$
\begin{aligned}
& \mathrm{R} 2=119 \Omega \text { and } \mathrm{R} 1=86 \Omega \text { thus: } \\
& \mathrm{I}_{\mathrm{OHmax}}=23 \mathrm{~mA} \text { and } \mathrm{I} \mathrm{OLmin}=3.0 \mathrm{~mA}
\end{aligned}
$$

Plugging in these values for the equations at the other extreme for $\mathrm{V}_{\mathrm{CC}}=5.25 \mathrm{~V}$ yields:

$$
\mathrm{V}_{\mathrm{TT}}=3.05 \mathrm{~V}, \mathrm{I}_{\mathrm{OHmax}}=28 \mathrm{~mA} \text { and } \mathrm{I}_{\mathrm{OL} \min }=5.2 \mathrm{~mA}
$$

Although the output currents are slightly higher than nominal, the potential for performance degradation is much less and the results of any degradation present will be significantly less dramatic than would be the case when the output emitter follower is cutoff. Again in most cases the component manufactures will provide devices with typical output levels; typical levels significantly reduces any chance of problems. However it is important that the system designer is aware of where any potential problems may come from so they can be dealt with during the initial design.

## Differential ECL Termination

Differential ECL outputs can be terminated using two different strategies. The first strategy is to simply treat the complimentary outputs as independent lines and terminate them as previously discussed. For simple interconnect between devices on a single board or short distances across the backplane this is the most common method used. For interconnect across larger distances or where a controlled impedance backplane is not available the differential outputs can be distributed via twisted pair of ribbon cable (use of ribbon cable assumes every other wire is a ground so that a characteristics impedance will arise). Figure 4 illustrates common termination techniques for twisted pair/ribbon cable applications. Notice that Thevenin equivalent termination techniques can be extended to twisted pair and ribbon cable applications as pictured in Figure 4. However for twisted pair/ribbon cable applications the standard termination technique picture in Figure 4 is somewhat simpler and also does not require a separate termination voltage supply. If however the Thevenin techniques are necessary for a particular application the following equations can be used:

$$
\begin{aligned}
& \mathrm{R} 1+\mathrm{R} 2=\mathrm{Z}_{\mathrm{O}} / 2 \\
& \mathrm{R} 3=\mathrm{R} 1\left(\mathrm{~V}_{\mathrm{T}}-\mathrm{V}_{\mathrm{EE}}\right) /\left(\mathrm{V}_{\mathrm{OH}}+\mathrm{V}_{\mathrm{OL}}-2 \mathrm{~V}_{\mathrm{TT}}\right) \\
& \mathrm{V}_{\mathrm{TT}}=\left(\mathrm{R} 3\left\{\mathrm{~V}_{\mathrm{OH}}+\mathrm{V}_{\mathrm{OL}}\right\}+\mathrm{R} 1\left\{\mathrm{~V}_{\mathrm{EE}}\right\}\right) /(\mathrm{R} 1+2 \mathrm{R} 3)
\end{aligned}
$$

where $\mathrm{V}_{\mathrm{OH}}, \mathrm{V}_{\mathrm{OL}}, \mathrm{V}_{\mathrm{EE}}$ and $\mathrm{V}_{\mathrm{TT}}$ are PECL voltage levels.
Plugging in the various values for $\mathrm{V}_{\mathrm{CC}}$ will show that the $\mathrm{V}_{\mathrm{T}}$ tracks with $\mathrm{V}_{\mathrm{CC}}$ at a rate of approximately 0.7:1. Although this rate is approaching ideal it would still behoove the system designer to ensure there are no potential situations where the output emitter follower could become cutoff. The calculations are similar to those performed previously and will not be repeated.

## Noise and Power Supply Distribution

Since ECL devices are top rail referenced it is imperative that the $V_{\text {CC }}$ rail be kept as noise free and variation free as
possible. To minimize the $V_{C C}$ noise of a system liberal bypassing techniques should be employed. Placing a bypass capacitor of $0.01 \mu \mathrm{~F}$ to $0.1 \mu \mathrm{~F}$ on the $\mathrm{V}_{\mathrm{CC}}$ pin of every device will help to ensure a noise free $\mathrm{V}_{\mathrm{CC}}$ supply. In addition when using PECL in a system populated heavily with CMOS and TTL logic the two power supply planes should be isolated as much as possible. This technique will help to keep the large current spike noise typically seen in CMOS and TTL drivers from coupling into the ECL devices. The ideal situation would be multiple power planes; two dedicated to the PECL $V_{C C}$ and ground and the other two to the CMOS/TTL VCC and ground. However if these extra planes are not feasible due to board cost or board thickness constraints common planes with divided subplanes can be used (Figure 5). In either case the planes or sub planes should be connected to the system power via separate paths. Use of separate pins of the board connectors is one example of connecting to the system supplies.

Parallel Twisted Pair Termination

Thevenin Twisted Pair Termination
Figure 4. Twisted Pair Termination Techniques
For single supply translators or dual supply translators which share common power pins the package pins should be connected to the ECL $V_{C C}$ and ground planes to ensure the noise introduced to the part through the power plane is minimal. For translating devices with separate TTL and ECL

individual device level
power supply pins, the pins should be tied to the appropriate power planes.

Another concern is the interconnect between two cards with separate connections to the $\mathrm{V}_{\mathrm{CC}}$ supply. If the two boards are at the opposite extremes of the $\mathrm{V}_{\mathrm{CC}}$ tolerance, with the driver being at the higher limit and the receiver at the lower limit, there is potential for soft saturation of the receiver input. Soft saturation will manifest itself as degradation in AC performance. Although this scenario is unlikely, again the potential should be examined. For situations where this potential exists there are devices available which are less susceptible to the saturation problem. This variation in $\mathrm{V}_{\mathrm{CC}}$ between boards will also lead to variations in the input switching references. This variation will lead to switching references which are not ideally centered in the input swing and cause rise/fall skew within the receiving device. Obviously the later skew problem can be eliminated by employing differential interconnect between boards.

When using PECL to drive signals across a backplane, situations may arise where the driver and the receiver are on different power supplies. A potential problem exists if the receiver is powered down independent of the driver. Figure 6 (on the following page) represents a generic driver/receiver pair. From Figure 6, one can see if the receiver is powered down and presents a path to ground through its $\mathrm{V}_{\mathrm{CC}}$ pin while the driver is still powered at +5.0 V the base/collector junction of the input transistor of the receiver will be forward biased and conduct current. Although the collector load resistor will limit the current in the situation of Figure 6, the current may still be enough to damage the junction or exceed the current handling capability of the base electrode metal stripe. Either of these situations could lead to degradation of the reliability of the
devices. Because different devices have different ESD protection schemes, and input architectures, the extent of the potential problem will vary from device to device.
Another issue that arises in driving backplanes is situations where the input signals to the receiver are lost and present an open input condition. Many differential input devices will become unstable in this situation, however, most of the newer designs, and some of the older designs, incorporate internal clamp circuitry to guarantee stable outputs under open input conditions. All of the ECLinPS (except for the E111), ECLinPS Lite, and H600 devices, along with the MC10125, 10H125 and 10114 will maintain stable outputs under open input conditions.

## Conclusion

The use of ECL logic has always been surrounded by clouds of misinformation; none of those clouds have been thicker than the one concerning PECL. By breaking through this cloud of misinformation the traditional CMOS/TTL designers can approach system problems armed with a complete set of tools. For areas within their designs which require very high speed, the driving of long, low impedance lines or the distribution of very low skew clocks, designers can take advantage of the built in features of ECL. By incorporating this ECL logic using PECL methodologies this inclusion need not require the addition of more power supplies to unnecessarily drive up the cost of their systems. By following the simple guidelines presented here CMOS/TTL designers can truly optimize their designs by utilizing ECL logic in areas in which they are ideally suited. Thus bringing to market products which offer the ultimate in performance at the lowest possible cost.

# ECLinPS ${ }^{\text {TM }}$ I/O SPICE Modeling Kit 

Prepared by
Todd Pearson
ECLinPS Applications Engineering

This application note provides the SPICE information necessary to accurately model system interconnect situations for high speed ECLinPS designs. The note includes information on both the standard ECLinPS family, as well as the ECLinPS Lite products.

MOTOROLA

# ECLinPS I/O SPICE Modeling Kit 

## Objective

The objective of this kit is to provide customers with enough circuit schematic and SPICE parameter information to allow them to perform system level interconnect modeling for the Motorola ECLinPS and ECLinPS Lite logic families. The ECLinPS and ECLinPS Lite families are Motorola's highest performance ECL families. With packaged gate delays of 300ps and output edge rates as low as 175ps these two families define the state-of-the-art in ECL logic. This kit is not intended to provide the user with the information necessary to perform extensive device modeling for any particular ECLinPS or ECLinPS Lite device. If users wish to perform the latter type of SPICE modeling they are encouraged to contact an ECLinPS Applications Engineer to obtain more detailed schematics and SPICE parameter information or order Motorola Application Note AN1560/D, Low Voltage ECLinPS SPICE Modeling Kit, from the Motorola Literature Distribution Center.

## Schematic Information

The kit contains representative schematics for the different I/O circuits used in the ECLinPS and ECLinPS Lite families. In addition a worst case package model schematic is included for more accurate system level modeling. The package model represents the parasitics as they are seen on a corner pin, a sizable distance from an AC ground. If more typical values are desired a $20 \%$ reduction in the capacitance and the inductance of the package model can be used. This package model should be placed on all external inputs to the input gates, all outputs of the output gates and on the $\mathrm{V}_{\mathrm{CC}}$ line. If desired the model can also be placed on the $\mathrm{V}_{\text {EE }}$ line, however this is not necessary due to the static nature of $\mathrm{V}_{\mathrm{EE}}$.

There is only one schematic, Figure 1, to represent the input structures of the family. For interconnect purposes this one schematic will adequately represent all of the ECLinPS devices except the differential input devices and the simple gates. The schematic in Figure 1 can be modified to represent differential devices by simply adding the package model and the ESD structure to the "VBB" input and using this as the inverted signal input. For the simple gates the input gate is actually the output gate represented by Figure 2. Therefore these devices should be modelled with the circuit of Figure 2 with the appropriate package model and ESD circuitry from Figure 1 added to the schematic. For the devices in the ECLinPS Lite family outlined in the appendix whose output and input buffers are one in the same the ESD circuitry and package models should be added to the appropriate output buffer. A list of devices which incorporate this structure is included in the appendix of this document.

There are five basic output structures needed to represent both families. The structure in Figure 2 mentioned above represents the structure used in the majority of the family, a simple $50 \Omega$ drive output cell. Figures 3 and 4 represent the special output functions used in the ECLinPS and ECLinPS

Lite families. Figure 3 shows the circuit configuration for a multiple output device (ie E112). Notice the doubling of the gate current necessary to drive the multiple output emitter followers. Figure 4 is the typical bidirectional $25 \Omega$ output structure used for the two bus driving functions currently in the ECLinPS family. Notice the doubled output emitter follower (OEF). This is necessary to provide a small enough $V_{B E}$ to produce an acceptable $\mathrm{V}_{\mathrm{OH}}$ level while providing the current necessary for $25 \Omega$ drive. In addition the collector load resistors have been increased to provide a cutoff $\mathrm{V}_{\mathrm{OL}}$. Due to the larger collector load resistor the gate current is increased $3 x$ to reduce the relative size of the collector load resistors so that the $\mathrm{I}_{\mathrm{b}}$ of the OEF does not produce an $\mathrm{I}_{\mathrm{R}}$ drop across the collector load resistor sufficient to create a marginal $\mathrm{V}_{\mathrm{OH}}$.

The schematics in Figures 5 and 6 represent the bandwidth enhanced ECLinPS and ECLinPS Lite devices. Because the bandwidth of standard ECLinPS devices are limited by their rise and fall times, the bandwidth can be enhanced by simply using higher current levels in the output buffers. This added current allows the parasitic capacitances of the gate to charge and discharge more quickly, thus enhancing the transition time performance of the device. Thus far two levels of gate current increase have been used to reach two different plateaus of performance. The majority of the enhanced bandwidth ECLinPS and ECLinPS Lite devices utilize the $2 x$ current increase of Figure 4. A full outline of the devices which utilize these buffers can be found in the appendix.

The schematics of Figure 7 represent the temperature compensation networks present in the output structures for 100E devices. The output buffer schematics all reference one of the temperature compensation networks. The temperature compensation circuitry should be placed as pictured in the output buffer schematics with $L$ and $R$ representing left and right of the schematic. Obviously for 10E circuit outputs these networks can be ignored. Also included in the appendix is the package model of Figure 8 and the ESD circuitry of Figure 9. The ECLinPS ESD should be added to any input of an ECLinPS device being driven by a signal off chip. The ECLinPS Lite ESD should be added to both the inputs and outputs for any ECLinPS Lite device being modelled. Finally the appropriate package model (8-lead SOIC for ECLinPS Lite or 28-lead PLCC for ECLinPS) should be included on all input and output pins and at least the VCC power supply.

Both the typical and multiple output circuits show differential inputs and outputs. If the user is simulating a single ended device the OEF and associated package model and load resistor of the unneeded output should be deleted from the schematic. If the user chooses to drive an output cell directly instead of using the input cell either of the following two driving approaches can be used:

|  | IN | VBB | Rise/Fall |
| :--- | :---: | :---: | :---: |
| Diff | $-1.2 \mathrm{~V}>-1.6 \mathrm{~V}$ | $-1.6 \mathrm{~V}>-1.2 \mathrm{~V}$ | $180 \mathrm{ps}(20 \%-80 \%)$ |
| S.E. | $-0.9 \mathrm{~V}>-1.75 \mathrm{~V}$ | -1.325 V | $180 \mathrm{ps}(20 \%-80 \%)$ |

## SPICE Parameter Information

In addition to the schematics a listing of the SPICE parameters for the transistors referenced in the schematics is included. These parameters represent a typical device of the given transistor size. Varying these parameters will obviously affect the voltage levels, the propagation delays, and the transition times of a device. For the type of modeling for which this information is intended the actual propagation delay of a device will not be modelled, as a result variations in this parameter are meaningless. Furthermore the voltage levels and transition times can be more easily varied by other means. This will be addressed in the next section.

All of the resistors referenced in the schematics are polysilicon resistors and thus there is no need to provide parasitic capacitance models for these resistors in the netlist. The only devices needed in the SPICE netlist are illustrated in the schematics.

## modeling Information

The bias driver schematics are not included as they were deemed unnecessary for interconnect simulation, in addition their use also results in a relatively large increase in simulation time. Alternatively the internal reference voltages ( $\mathrm{V}_{\mathrm{BB}}$ and $\mathrm{V}_{\mathrm{CS}}$ ) should be driven with ideal constant voltage sources. The following table summarizes the voltage levels for these internal references as well typical input voltage parameters.

| Parameter | Typical Level | Worst Case |
| :--- | :---: | :---: |
| $\mathrm{V}_{\mathrm{BB}}$ | -1.325 V | Data Book |
| $\mathrm{V}_{\mathrm{CS}}$ | V EE +1.33 V | $\pm 50 \mathrm{~V}$ |
| $\mathrm{~V}_{\text {IH }}$ | $-0.9 \mathrm{~V}(10 \mathrm{E}) ;-0.95 \mathrm{~V}(100 \mathrm{E})$ | Data Book |
| $\mathrm{V}_{\mathrm{IL}}$ | $-1.75 \mathrm{~V}(10 \mathrm{E}) ;-1.7 \mathrm{~V}(100 \mathrm{E})$ | Data Book |
| Rise/Fall | $400 \mathrm{ps}(20 \%-80 \%)$ | Data Book |

The schematics and SPICE parameters provided will provide a somewhat typical output waveshape which may not represent the worst case system situation. Fortunately there are some simple adjustments that can be made to the
schematics to provide output characteristics at or near the corners of the data book specification limits. First to adjust the $\mathrm{V}_{\mathrm{OH}}$ level one simply needs to lower the $\mathrm{V}_{\mathrm{CC}}$ value below ground by the amount one wishes to alter the VOH level. This $\mathrm{V}_{\mathrm{CC}}$ adjustment will obviously also result in a change in the $\mathrm{V}_{\mathrm{OL}}$ level. To change the $\mathrm{V}_{\mathrm{OL}}$ level independent of the $\mathrm{V}_{\mathrm{OH}}$ level the collector load resistors can be increased or decreased depending on the change desired (Note: $\mathrm{V}_{\mathrm{OH}}$ will change slightly due the the $\mathrm{l}_{\mathrm{b}} \mathrm{R}$ drop portion of the $\mathrm{V}_{\mathrm{OH}}$ level). The $\mathrm{V}_{\mathrm{OL}}$ can also be changed by increasing/decreasing the current in the gate via the current source resistor. In addition to changing the $\mathrm{V}_{\mathrm{OL}}$ level, by increasing/decreasing the gate current the output rise and fall times will decrease/increase due to the additional current available to charge and discharge the stray capacitance on the collectors of the output differential pair. If the user would like to adjust the levels and transition times of an output gate to represent a corner of the guaranteed specification the following sequence should be followed:

1) Adjust the gate current to produce the desired output slew rate
2) Adjust the $V_{\mathrm{CC}}$ for the desired $\mathrm{V}_{\mathrm{OH}}$
3) Adjust the collector load resistor for the desired $\mathrm{V}_{\mathrm{OL}}$

## Summary

The information included in this kit should provide the user with all of the information necessary to do SPICE level system interconnect modeling. The block diagram of Figure 10 illustrates the type of situation which can be effectively modelled using the ECLinPS I/O SPICE modeling Kit. The schematic information provided in this document is available in netlist form through EMAIL or an IBM or Macintosh disk, although with today's advanced design tools it will probably be a simpler task to enter the schematics in a good schematic capture package than it would be to manipulate the generic netlist. If however the netlist are desired, clarification is needed or additional information is necessary the user is encourage to contact any ECLinPS Application Engineering personnel for assistance.

## AN1504 <br> Application Note

# Metastability and the ECLinPS ${ }^{\text {TM }}$ Family 

Prepared by
Rennie Wm. Dover
Todd Pearson
ECLinPS Applications Engineering

This application note examines the concept of metastability and provides a theoretical discussion of how it occurs, including examples of the metastable condition. An equation characterizing metastability and a test circuit derived from that equation are presented. Metastability results are then applied to the ECLinPS family.

## Metastability and the ECLinPS Family

## Introduction

Metastability is a central issue anytime a designer wishes to synchronize two or more asynchronous signals. A popular method for accomplishing this task is to employ a D flip-flop as the synchronizing element (Figure 1).

As shown in Figure 1, synchronization can be accomplished using a single D flip-flop; more typically, several D flip-flops are cascaded to provide synchronization while reducing the probability of a metastable or "anomalous" state occurring at the input of System 2. Unfortunately the information at the data and clock inputs of flip-flops used as synchronizing elements is asynchronous by nature, thus the manufacturer specifications for set-up and hold times may not be observed. A series of timing diagrams is shown in Figure 2 demonstrating three possible timing relationships between the data and clock signals; to the right of each data trace is the corresponding output waveform. In the first case the data adheres to the specified set-up and hold times, hence the output attains the proper state. In case 2 the set-up time is violated such that the output of the $D$ flip-flop does not change
state. Case 3 represents a violation of the set-up and hold times whereby the D flip-flop enters a metastable state. The resolving time for a flip-flop in this metastable state is indeterminate. Further, the final settling state of the flip-flop having been in this metastable condition cannot be guaranteed.

## Metastability Theory

A bistable device such as a flip-flop has two stable output states: the " 1 " or high state and the " 0 " or low state. When the manufacturers specified set-up and hold times are observed the flip-flop will achieve the proper output state (Figure 3). However if the set-up and hold times are violated the device may enter a metastable state, thereby increasing the propagation delay, as indicated by the output response shown in Figure 4.

To better understand flip-flop metastability, the operation of a typical ECLinPS D flip-flop is reviewed. The schematic of a D flip-flop is shown in Figure 5.

Figure 1. Clock Synchronization Schemes

Figure 2. Timing Relationships Between Data and Clock Signals for a D Flip-Flop

Figure 3. Typical Flip-Flop Output Response

Figure 4. Metastable Flip-Flop Output Response

The flip-flop shown in Figure 5 can be divided into two functional blocks: Master latch and Slave latch. Under optimal operating conditions the clock is low when data arrives at the input to the master latch; after the specified set-up time the clock input is raised to a high level, and the data is latched. When the clock signal goes to the low state, the slave portion of the circuit becomes transparent and transfers the latched data to the output. Changes at the input will have no affect on the output when the "slave latch" is transparent.

The master and slave latches each consist of two subsections: Data and Regenerative (Figure 5). Since the master latch accepts signals from external sources it is the section most susceptible to metastability problems. When the clock signal goes to a high state the current in the master latch
clock differential pair switches from the regenerative to the data side. If the set-up and hold times are observed the circuit will function properly. However, if the data and clock signals change such that the set-up and hold times are violated, the data differential pair, the regenerative differential pair and the clock differential pair for the master will share the same switch current. In addition there will not be enough current to charge and discharge the transistor parasitic capacitances, creating an RC feedback loop via the collector nodes of the data and regenerative differential pairs. Thus the master latch enters a metastable state which appears at the output since the slave latch is transparent under these conditions. Theoretically, there is no upper bound on the length of time this metastable state can last, although in practice circuits eventually do leave the metastable region.

Figure 5. ECLinPS D Flip-Flop

## Metastable Equations

Flip-flop propagation delay as a function of the input signal is represented in Figure 6.

Figure 6. Flip-Flop Response Time Plot
The ordinate is the flip-flop propagation delay time, and the abscissa is the time that data arrives at the flip-flop input relative to reference time, $\mathrm{T}_{0}$. For devices with positive set-up times $\mathrm{T}_{0}$ represents the clock transition time with the difference between $T_{0}$ and $T_{\text {MAX }}$ being the minimumallowable set-up time. Thus data arriving before time TMAX will elicit a nominal propagation delay, $\mathrm{T}_{\mathrm{p}}$, when clocked. For data appearing between times $T_{M A X}$ and $T_{F}$ the propagation delay will be longer than $T_{p}$ because the set-up and/or hold times have been violated; and the device enters the metastable
state. Data occurring at the input after time $T_{F}$ will have no affect on the output, hence the output does not change and the propagation delay is defined as zero.

For devices with zero or negative set-up times the same response plot applies, however the abscissa is shifted such that the value of TO is no longer the clock transition time. The same concepts are valid for derivation of metastability equations for each case: positive, negative or zero set-up and hold times. To clarify the flip-flop response plot, Figure 7a illustrates a case in which the propagation delay is $T_{p}$. Data arrives at time $\mathrm{T}_{\mathrm{A}}$, allowing the proper set-up time prior to a clock transition and is maintained at this level for the specified hold time. Figure 7 b is an example in which the propagation delay is longer than $T_{P}$ since the data arrives at time $T_{A}$, violating the set-up time.

Using the response plot in Figure 6, Stoll ${ }^{1}$ developed the concept of a failure window to facilitate the characterization of metastability. The value of $T_{W}\left(T_{D}\right)$ is the width of the window for which a propagation delay of time duration $T_{D}$ occurs, and is the range of data input times relative to the clock input for which a failure will occur. The value of $T_{D}$ is the maximum allowable propagation delay; delays longer than $T_{D}$ constitute a failure. The failure window is described mathematically as:

$$
\begin{equation*}
\mathrm{TW}(\mathrm{TD})=\mathrm{TP}^{*} 10-(\Delta \mathrm{t}) / \tau \tag{eqt1}
\end{equation*}
$$

| Where: | $T_{W}\left(T_{D}\right)$ |
| :---: | :--- |
| $\mathrm{TP}_{\mathrm{D}}$ | Failure Window Width |
| $\mathrm{T}_{\mathrm{D}}$ | Nominal Propagation Delay |
|  | Delay After Clock That |
| $\tau$ | Constitutes a Failure |
| $\Delta \mathrm{t}$ | Flip-Flop Resolution Time Constant |
|  | Excess Delay (TD $\left.-T_{P}\right)$ |

Figure 7b. Violation of Set-Up and Hold Times

This equation only applies for narrow window widths i.e. those times well up on the response plot of Figure 6.

To summarize, when the set-up and hold times are obeyed the flip-flop will have a nominal propagation delay, Tp. If the data and clock signals arrive such that the set-up and hold times are violated there will be an excess delay as indicated in the response plot of Figure 6. This excess delay is caused by the flip-flop entering the metastable region. For data signals arriving much later than the clock signal the flip-flop will not change state, thus the propagation delay is zero by definition. The window width is the range of input arrival times relative to the clock for which the output response does not attain a defined value within the time period $T_{D}$. Since $T_{D}$ represents the maximum allowable delay, the window width represents the relative range of input times for which a failure will occur.

Equation 1 can be combined with the industry accepted definition for system level Mean Time Between Failures (eqt. $2)^{2}$ to derive an equation yielding Mean Time Between Failures as a function of system design and semiconductor device parameters.

$$
\begin{equation*}
\text { MTBF }=1 /\left(2^{\star} f C^{*} f D^{*} T W(T D)\right) \tag{eqt2}
\end{equation*}
$$

| Where: | ${ }_{\mathrm{f}}^{\mathrm{f}} \mathrm{C}$ |
| ---: | :--- |$\quad$| Clock Frequency |
| :--- |
| D |$\quad$ Data Frequency

$$
\begin{equation*}
\text { MTBF }=1 /\left(2^{\star} \mathrm{f}^{\star} \mathrm{f}^{*} \mathrm{D}^{*} \mathrm{P}^{*} 10^{-(\Delta \mathrm{t}) / \tau)}\right. \tag{eqt3}
\end{equation*}
$$

The system's designer can use Equation 3 to address the issue of metastability. $\tau$ and $T_{P}$ are provided in the ECLinPS Data Book (DL140/D). MTBF, $f_{C}$ and $f_{d}$ are system design parameters. Thus the designer can use this equation to determine the value of $T_{D}$.

## Test Circuitry For Metastable Evaluation

Equation 3 provides the impetus for the design of a metastability test circuit capable of providing a value of $\tau$, the flip-flop resolution time constant. Transforming this equation into a "linear" form by taking the logarithm of both sides yields Equation 4:

$$
\begin{equation*}
\log M T B F=-\log \left(2^{\star} C^{*} C^{*} D^{*} T P\right)+\Delta t / \tau \tag{eqt4}
\end{equation*}
$$

Plotting $\log$ MTBF versus $\Delta t$ yields a line with slope $1 / \tau$, and $\log$ MTBF intercept of $-\log \left(2^{\star} f_{c}{ }^{*} f d^{*} T p\right)$. Thus, the test circuit must accept the clock and data input frequencies as a function of $\Delta t$ and yield MTBF as an output. The circuit configuration shown in Figure 8 fulfills these criteria.

The test circuitry can be categorized into five functional blocks: DUT, adjustable delay portion, comparator section, counter-set circuitry, and the counter. Starting with the comparator portion of the circuit, the output of the DUT is fed into the comparator; if the DUT output falls in the range $\mathrm{V}_{\mathrm{BB}}$ 0.15 volts $<\mathrm{V}_{\mathrm{BB}}<\mathrm{V}_{\mathrm{BB}}+0.15$ volts, the DUT is defined as being in a metastable condition(Fig. 9).

For DUT output states in the metastable region the comparator output attains a logic high level. When the DUT output does not fall within this range it is in a "defined high or low level," and the output of the comparator will be at a logic low level. If the comparator output is at a logic high level, indicating metastability, the counter-set section sends out a periodic waveform which increments the counter. If the DUT is not metastable the output of the "counter-set" circuitry is constant and the counter (HP-8335A) is not incremented. The total number of counts over a specified time period is a measure of MTBF.

Figure 8. Metastability Test Circuit

Pulse generator \#1 (PG 1) supplies the data signal to the DUT. To ensure asynchronous signals between the DUT data and clock signals, a separate pulse generator, PG2, provides the clock signal to the DUT. Generator PG2 also provides the clocking signal to the comparator circuitry via its inverting output terminal. Pulse generator PG3 supplies the clock signals to the E451 portion of the comparator section. To increase the probability of the DUT entering the metastable state the DUT data frequency is set at 1.33 times the DUT clock frequency. The value of $\Delta t$ is the delay between the noninverting clock signals for the DUT and the E451. Finally, the inverting terminal of PG2 supplies the clock signal for the counter-set circuitry.

Figure 9. Output Response Defining the Metastable Region

To take advantage of the precision $50 \Omega$ input impedance of the test measurement equipment, the circuit power supplies are shifted by +2.0 volts. Thus all input signals, bias voltages, and comparator values have been shifted by +2.0 volts as shown in Table 1.

Table 1. ECL Levels After Translating by +2.0V

|  | Typical (V) |  | Shifted (V) |  |
| :--- | :---: | :---: | :---: | :---: |
| Parameter | 10E | 100 E | 10E | 100 E |

## Results

An example of using a log MTBF versus $\Delta t$ plot to determine $\tau$ is shown in Figure 10.

Figure 10. Plot of Log MTBF versus Delay

From Equation 4 the slope of the line is the reciprocal of $\tau$. Measurements similar to these were performed to characterize the ECLinPS family as well as D flip-flops from various vendors. The results are shown in Table 2:

Table 1. $\tau$ Values for Several Flip-Flops

| Device Type | $\tau$ |
| :--- | :---: |
| Motorola 10E431 | 125 psec |
| Motorola 10E151 | 185 psec |
| Motorola 10E131 | 200 psec |
| Motorola 10H131 | 718 psec |
| Signetics 100131 | 890 psec |
| Signetics 100151 | 1172 psec |
| National 100131 | 1594 psec |

Having determined the value of $\tau$, the system designer can use this information in conjunction with Equation 3 to aid in optimizing the system design.

## Example

As an example, assume the system configuration shown in Figure 11, in which the output from System 1 is to be synchronized to System 2 using a 10E151 D flip-flop.

Further, the equivalent output signal for System 1 is 75 MHz whereas the clock frequency for System 2, as well as the synchronizing element, is 100 MHz . Under these conditions the data and clock inputs to the D flip-flop are asynchronous and the system designer must consider the possibility of the $D$ flip-flop entering the metastable state. Therefore the system designer must determine how long the flip-flop will remain in the metastable region in order to decide when the data at the output of the flip-flop will attain a defined state and can be clocked into System 2.

AN1504

The solution to this dilemma is found with Equation 3:

$$
\text { MTBF }=1 /\left(2^{*} \mathrm{f}^{*} \mathrm{C}^{*} \mathrm{D}^{*} \mathrm{TP}^{*} 10-(\Delta \mathrm{t}) / \tau\right)
$$

The values for fc and fd were specified as 100 MHz and 75 MHz , respectively. Assuming the D flip-flop is a Motorola 10E151, a worse case value of propagation delay (Tp) of 800 psec is obtained from the ECLinPS Device Data Book. The value of $t$ is given in Table 2 as 185 psec . Substituting these values into Equation 3 yields:

$$
\text { MTBF }=1 /\left(2^{*} \mathrm{f}^{*} \mathrm{ff}^{*} \mathrm{D}^{\star} \mathrm{P}^{*} 10-(\Delta \mathrm{t} / 185 \mathrm{psec})\right)
$$

At this point the system designer must specify an acceptable MTBF. For this example an MTBF of 5 years is assumed. Therefore the value of $\Delta t$ is calculated to be

$$
\Delta t=2.83 \mathrm{nsec}
$$

From the relationship

$$
\Delta t=T D-T P
$$

the value of $T_{D}$ is calculated to be
TD $=3.63 \mathrm{nsec}$

Thus for an MTBF of 5 years the designer should delay the clocking of the data from the output of the flip-flop into System 2 by 3.63 nsec .

## Conclusion

Metastability has become a critical issue with system designers. In order to better serve our customers, Motorola has characterized the ECLinPS family for metastability using the concept of a failure window. The nominal flip-flop resolution time constant for the ECLinPS family, excluding the E131 and E431 devices as these flip-flops use alternative architectures, has been determined to be 185 psec. The resolution time constant for the E131 and E431 devices is 200 psec and 125 psec, respectively. Thus the system designer can use the value of $\tau$ in conjunction with Equation 3 to determine the metastable induced excess delay for a specified MTBF. Although this application note does not present a method for avoiding metastability, it does provide a means for the designer to quantitatively incorporate metastability in their designs.

# Interfacing Between LVDS and ECL 

Andrea Diermeier
Motorola Logic Engineering

# Interfacing Between LVDS and ECL 

## Introduction

LVDS (Low Voltage Differential Signaling) signals are used to interface between today's CMOS or BiCMOS ASICs supplied with 3.3V. LVDS signals are differential signals with a swing of 250 to 400 mV and a DC offset of 1.2V. External components are required for board to board data transfer or clock distribution.

In advanced systems often only a single supply voltage (3.3V) is available. Low Voltage ECL devices work off this 3.3 V supply voltage in the so called LVPECL mode. Input/Output LVPECL levels are related to $\mathrm{V}_{\mathrm{CC}}=3.3 \mathrm{~V}-\mathrm{a}$ 750 mV output swing with 2 V offset. This makes them ideal as peripheral components for ASICs.

LVPECL and LVDS are both differential low voltage signals, but with different swing and different offset. The purpose of this application information is to show the interfacing between these signal levels. In addition it gives interface suggestions to and from 5V supplied PECL devices or negative supplied ECL.

Figure 1. Voltage Levels

## LVDS Levels

The LVDS levels have been specified by IEEE (IEEE un-approved Standard P1596.3). There are 2 different specifications, the general purpose specification with 250 to 400 mV swing and the super low power specification with reduced swing ( $150 \ldots 250 \mathrm{mV}$ ).

LVDS outputs require a $100 \Omega$ load between the differential outputs. This load will in addition terminate the $50 \Omega$ controlled impedance lines.

Figure 2. LVDS Output Definition

## ECL levels

In ECL circuits all signal levels are related to $\mathrm{V}_{\mathrm{CC}}$ supply rail. Traditional ECL designs are supplied with negative voltages with $\mathrm{V}_{\mathrm{CC}}=$ GND.

Today several applications use ECL devices in the PECL mode. PECL - Positive ECL is nothing more than supplying any ECL divide with a positive power supply $(+5 \mathrm{~V})$.

With the trend to low voltage systems a new generation of ECL circuitry has been developed. The Low Voltage ECL devices (LVECL) work from a 3.3V power supply either as negative supplied or more popular from standard $\mathrm{V}_{\mathrm{CC}}=$ +3.3 V and $\mathrm{V}_{\mathrm{EE}}=$ GND as LVPECL.

100E(L) type output DC levels for the different supply levels are shown in Table 2 on page 5-89.

Table 1. LVDS Levels

| Symbol | Parameter | General Purpose Specification |  | Super Low Power Specification |  | Unit | Condition |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  | Min | Max | Min | Max |  |  |

Transmitter

| $\mathrm{V}_{\mathrm{OH}}$ | Output HIGH Voltage |  | 1474 |  | 1374 | mV | $\mathrm{R}_{\mathrm{L}}=100 \Omega$ |
| :--- | :--- | :---: | :---: | :---: | :---: | :---: | :--- |
| $\mathrm{~V}_{\mathrm{OL}}$ | Output LOW Voltage | 925 |  | 1025 |  | mV | $\mathrm{R}_{\mathrm{L}}=100 \Omega$ |
| $\mathrm{~V}_{\mathrm{PP}}$ | Output Differential Voltage | 250 | 400 | 150 | 250 | mV | $\mathrm{R}_{\mathrm{L}}=100 \Omega$ |
| $\mathrm{~V}_{\mathrm{OS}}$ | Output Offset Voltage | 1125 | 1275 |  |  | mV |  |

Receiver

|  | Input Voltage Range | 0 | 2400 | 0 | 2000 | mV | $V_{\text {gpd }}<950 \mathrm{mV}$ |
| :--- | :--- | :---: | :---: | :---: | :---: | :---: | :--- |
|  | Differential HIGH Input Threshold |  | +100 |  | +100 | mV | $\mathrm{V}_{\text {gpd }}<950 \mathrm{mV}$ |
|  | Differential LOW Input Threshold | -100 |  | -100 |  | mV | $\mathrm{V}_{\text {gpd }}<950 \mathrm{mV}$ |

Table 2. MC100Exxx/MC100ELxx ( $\mathrm{T}_{\mathrm{A}}=0^{\circ}-85^{\circ} \mathrm{C}$ )

| Symbol | Parameter | LVPECL | PECL ${ }^{2}$ | ECL | Unit |
| :--- | :--- | :---: | :---: | :---: | :---: |
| $\mathrm{V}_{\mathrm{CC}}$ |  | +3.3 | +5.0 | GND | V |
| $\mathrm{V}_{\mathrm{EE}}$ |  | GND | GND | $-5.2,-4.5$ or -3.3 | V |
| $\mathrm{~V}_{\mathrm{OH}}$ | Minimum Output HIGH Level | 2.275 | 3.975 | -1.030 | V |
| $\mathrm{~V}_{\mathrm{OH}}$ | Typical Output HIGH Level | 2.345 | 4.045 | -0.955 | V |
| $\mathrm{~V}_{\mathrm{OH}}$ | Maximum Output HIGH Level | 2.420 | 4.120 | -0.880 | V |
| $\mathrm{~V}_{\mathrm{OL}}$ | Minimum Output LOW Level | 1.490 | 3.190 | -1.810 | V |
| $\mathrm{~V}_{\mathrm{OL}}$ | Typical Output LOW Level | 1.595 | 3.295 | -1.705 | V |
| $\mathrm{~V}_{\mathrm{OL}}$ | Maximum Output LOW Level | 1.680 | 3.380 | -1.620 | V |

1. $V_{C C}$ assumed 3.3 V . All levels vary $1: 1$ with $V_{C C}$.
2. $\mathrm{V}_{\mathrm{CC}}$ assumed 5 V . All levels vary $1: 1$ with $\mathrm{V}_{\mathrm{CC}}$.

ECL outputs are open emitter outputs, requiring a DC path to a more negative supply than VOL. This pull down resistor termination can be used to terminate transmission lines application specific.

ECL standard DC input levels are related to $\mathrm{V}_{\mathrm{CC}}$. Several devices are available with so called common mode range inputs. These inputs allow to process signals with small swings down to $200 \mathrm{mV}, 150 \mathrm{mV}$ or even 50 mV signal levels within an offset range.

## Interfacing

Common mode range inputs are capable to process differential signals with 150 to 400 mV swing. The LVDS input processes signals up to 950 mV swing. The DC voltage levels should be within the input voltage range.

To interface between these 2 voltage levels capacitive coupling can be used. Only clock or coded signals should be capacitive coupled.

A capacitive coupling of NRZ signals will cause problems. Then passive or active interfacing is necessary.

## Capacitive Coupling LVDS to ECL

## Capacitive Coupling LVDS to ECL using VBB

Figure 3. Capacitive Coupling LVDS to ECL Using VBB

Several ECLinPS/ECLinPS Lite devices supply a $V_{B B}$ $\left(V_{B B} \approx V_{C C}-1.3 V\right)$ reference voltage. It can been used for differential capacitive coupling. $V_{B B}$ needs to be decoupled to GND via a 10 nF capacitance.

The $100 \mathrm{k} \Omega$ gives stable known behavior for all signal conditions.

## Capacitive Coupling LVDS to ECL with external biasing

If $V_{B B}$ reference voltage is not available a similar DC voltage can be generated with a resistor divider. The resistor values depend on $\mathrm{V}_{\mathrm{CC}} / \mathrm{V}_{\mathrm{EE}}$ voltages.

Figure 4. Capacitive Coupling LVDS to ECL with External Biasing
Examples:

In the layout for both interfaces the resistors and the capacitors should be located as close as possible to the ECL input.

## Capacitive Coupling ECL to LVDS

The ECL output requires a DC path. The pulldown resistors are connected to $\mathrm{V}_{\mathrm{EE}}$.

The thevenin resistor pair represent the termination of the transmission line $Z=R 1| | R 2$ and generates a DC level of 1.2V.

Figure 5. Capacitive Coupling LVDS to ECL

## Capacitive Coupling ECL to LVDS using VOS reference voltage

Some devices with LVDS interfaces supply $\mathrm{V}_{\mathrm{OS}}$ reference voltage. This can be used for capacitive coupling. Beside the transmission line length is very short, a parallel termination should be used and placed as close as possible to the coupling capacitors.

Figure 6. Capacitive Coupling LVDS to ECL Using VOS Reference Voltage

## Interfacing from LVPECL to LVDS

The DC output level of LVPECL is more positive than the input range of LVDS. All ECL devices need pulldown resistors. The pulldown resistors in a thevenin equation or pulldown resistors to GND can be split up into a resistor divider to generate LVDS levels.

Dependent on the application one of the following interfaces should be used:

Interfacing LVPECL to LVDS in thevenin equation

Figure 7. Interfacing LVPECL to LVDS in Thevenin Equation
The thevenin equation resistors terminate the transmission line $Z$ near the receiver (parallel termination). Instead of a resistor to $\mathrm{V}_{\mathrm{EE}}$, a resistive path to $\mathrm{V}_{\mathrm{CC}}$ and to $\mathrm{V}_{\mathrm{EE}}$ (GND) build the termination of the transmission line. In transmission line theory these resistors are in parallel for high frequency signals. They match the line characteristic impedance.
$R 1 \|(R 2+R 3)=Z$
Equation 1
The DC condition for point $A$ is $V_{C C}-2 \mathrm{~V}$. The $D C$ levels at the LVDS input (B) are located within the LVDS input common mode range.

$$
\begin{array}{lll}
\mathrm{A}: & \mathrm{R} 1 /(\mathrm{R} 1+\mathrm{R} 2+\mathrm{R} 3)=2 \mathrm{~V} / \mathrm{V}_{\mathrm{CC}} & \text { Equation } 2 \\
\mathrm{~B}: & \mathrm{R} 3 /(\mathrm{R} 1+\mathrm{R} 2+\mathrm{R} 3)=\mathrm{V}_{\mathrm{IL}} / \mathrm{V}_{\mathrm{CC}} & \text { Equation } 3
\end{array}
$$

The swing at the LVDS input is decreased dependent on R2 and R3

$$
\begin{aligned}
& \mathrm{V}_{\mathrm{ipp}}=\mathrm{R} 3 /(\mathrm{R} 2+\mathrm{R} 3) * \mathrm{~V}_{\mathrm{opp}} \\
& \mathrm{~V}_{\mathrm{IH}}<2.0 \mathrm{~V}(2.4 \mathrm{~V}) \\
& \mathrm{V}_{\mathrm{IL}}>0 \mathrm{~V}
\end{aligned}
$$

Calculations give non-standard resistor values. When choosing resistors off the shelf it should be considered to avoid a cutoff condition also under worst case supply voltage.

## Example:

For $50 \Omega$ controlled impedance lines $\mathrm{R} 1=120 \Omega, \mathrm{R} 2=33 \Omega$ and $R 3=51 \Omega$.

For any other controlled impedance line the calculation of the resistive divider is done according to Equation 1, Equation 2 and Equation 3.

## Interfacing LVPECL to LVDS with unterminated transmission line

Unterminated lines can be used for very short interconnects. For details about recommended maximum unterminated line length, see Motorola's High Performance ECL Data Book (DL140/D), chapter 4 "System Interconnects".

Figure 8. Interfacing LVPECL to LVDS with Unterminated Transmission Lines

The resistive divider reduces the offset of the signal to be processed by LVDS.

For example the following resistor values can be used:

$$
\begin{aligned}
& \mathrm{R} 1=56 \Omega \\
& \mathrm{R} 2=82 \Omega
\end{aligned}
$$

Parallel termination to GND is possible with a impedance matching resistor pair $(\mathrm{R} 1+\mathrm{R} 2=\mathrm{Z})$ using the Figure 8. Unfortunately this low impedance path causes a high output current. This will increase the device's power consumption. The increased die temperature has a negative impact on the statistic life time of the device.
Please Note: The maximum ratings of the output current may not be violated.

## Interfacing from LVDS to LVPECL

The common mode range inputs of the low voltage ECL line receivers are defined wide enough to process LVDS signals.

Figure 9. Interfacing LVDS to LVPECL
This direct interface is possible for all LVELxx devices with differential common mode range inputs, e.g. MC100LVEL17, MC100LVEL13, MC100LVEL14, MC100LVEL29, MC100LVEL39.

## Interfacing from PECL to LVDS

## Interfacing from PECL to LVDS using thevenin parallel termination

As described for LVPECL to interface from PECL to LVDS a thevenin equation termination is used.

Near the receiver a +5 V power supply connection is required.

Figure 10. Interfacing from PECL to LVDS Using Thevenin Equivalent Parallel Termination

$$
R 1 \|(R 2+R 3)=Z
$$

Equation 4
The $D C$ termination level at $A$ is $V_{C C}-2 V$. The $D C$ level of $B$ should be within the LVDS input common mode range.

$$
\begin{aligned}
& \mathrm{R} 1 /(\mathrm{R} 1+\mathrm{R} 2+\mathrm{R} 3)=2 \mathrm{~V} / \mathrm{V}_{\mathrm{CC}} \\
& \mathrm{R} 3 /(\mathrm{R} 1+\mathrm{R} 2+\mathrm{R} 3)=\mathrm{V}_{\mathrm{IL}} / \mathrm{V}_{\mathrm{CC}}
\end{aligned}
$$

Equation 5
Equation 6
The swing at the LVDS input is decreased dependent on R2 and R3

$$
\begin{aligned}
& \mathrm{V}_{\mathrm{ipp}}=\mathrm{R} 3 /(\mathrm{R} 2+\mathrm{R} 3)^{*} \mathrm{~V}_{\mathrm{opp}} \\
& \mathrm{~V}_{\mathrm{IH}}<2.0 \mathrm{~V}(2.4 \mathrm{~V}) \\
& \mathrm{V}_{\mathrm{IL}}>0 \mathrm{~V}
\end{aligned}
$$

Calculations give non standard resistor values. When choosing resistors off the shelf it should be considered to avoid a cutoff condition also under worst case condition.

If a $50 \Omega$ controlled impedance line is used the following resistor values are useful:

## Examples:

| $\mathrm{Z}=50 \Omega$ | $\mathrm{R} 1=82 \Omega$ | $\mathrm{R} 2=100 \Omega$ | $\mathrm{R} 3=33 \Omega$ |
| :--- | :--- | :--- | :--- |
| or |  |  |  |
| $\mathrm{Z}=50 \Omega$ | $\mathrm{R} 1=82 \Omega$ | $\mathrm{R} 2=82 \Omega$ | $\mathrm{R} 3=47 \Omega$ |

For any other controlled impedance line the calculation of the resistive divider is done according to Equation 4, Equation 5 and Equation 6.

## Interfacing from PECL to LVDS with unterminated lines

As described in LVPECL interfacing unterminated lines can be used for very short interconnections.
E.g. the resistors can be $R 1=330 \Omega, R 2=150 \Omega$.

## Interfacing from LVDS to PECL

To translate LVDS signals to PECL a differential LVE Lite device with extended common mode range inputs (e.g. MC100EL17) can be used to process and translate LVDS signals when supplied with $5 \mathrm{~V} \pm 5 \%$ supply voltage.

Figure 12. Interfacing from LVDS to PECL

Figure 11. Interfacing from PECL to LVDS with Unterminated Lines

Figure 13. Interfacing from Negative Supplied ECL to LVDS

Figure 14. Interfacing from LVDS to Negative Supplied ECL

## Interfacing Between Negative Supplied ECL and LVDS

Motorola has developed level translators to interface between the different ECL levels. The MC100LVEL/EL90 translates from negative supplied ECL to LVPECL. The interface from LVPECL to LVDS inputs is done as described above. For $-4.5 /-5.2 \mathrm{~V}$ power supplies the MC100EL90 is
used, for $-3.3 V$ supplies the MC100LVEL90.
To interface from LVDS to negative supplied ECL the common mode range of the MC100LVEL91 for -3.3 V supply and the MC100EL91 for $-4.5 /-5.2 \mathrm{~V}$ supply is wide enough to process LVDS signals.

If a +5 V supply and a $\mathrm{V}_{\mathrm{EE}}=-5.2 \mathrm{~V} \pm 5 \%$ supply is available the MC10E1651 can be used.

[^0]:    * Available in 10EL version only. † Available in 100ELT version only.
    ** Available in 100 EL version only.

[^1]:    * Any reference to ECLinPS in this section includes the ECLinPS Lite and Low Voltage ECLinPS families.

[^2]:    KEY:
    I designates an input
    O designates an output
    $\mathrm{V}_{\mathrm{EE}}$ designates the lower voltage rail
    $\mathrm{V}_{\mathrm{CC}}$ designates the upper voltage rail
    NC designates a no connect
    VB designates $\mathrm{V}_{\mathrm{BB}}$ output which should not be terminated into 50 ohms

[^3]:    1. Applies to the input current for each input except VCOIN
    2. For a nominal set current of 3.72 mA , the resistor values for RSETUP and RSETDN should be $130 \Omega(0.1 \%)$. Assuming no variation between these two resistors, the current match between the PUMPUP and PUMPDN output signals should be within $\pm 3 \%$. ISET is calculated as ( $V_{E E}+$ $\left.1.3 v-V_{B E}\right) / R$; where $R$ is RSETUP or RSETDN and a nominal value for $V_{B E}$ is 0.85 volts.
    3. Output leakage current of the PUMPUP or PUMPDN output signals when at a LOW level.
    4. TVCO is the period of the VCO.
    5. The VCO frequency determined with $\mathrm{VCOIN}=\mathrm{V}_{\mathrm{EE}}+0.5$ volts and using a 10 pF tuning capacitor.
    6. The tuning ratio is defined as the ratio offVCOMAX to $\mathrm{F}_{V C O M I N}$ where V VCOMAX is measuredat $\mathrm{VCOIN}=1.3 \mathrm{~V}+\mathrm{V}_{\mathrm{EE}}$ and VCOMAX is measured at $\mathrm{VCOIN}=2.6 \mathrm{~V}+\mathrm{V}_{\mathrm{EE}}$.
[^4]:    * On next negative transition of CLK or SCLK

[^5]:    1. Specifications for standard TTL input signal.
[^6]:    This document contains information on a product under development. Motorola reserves the right to change or discontinue this product without notice.

[^7]:    * On next negative transition of CLK or SCLK

[^8]:    1. All other DC characteristics are the same as Standard 100 K ECL.
[^9]:    This document contains information on a product under development. Motorola reserves the right to change or discontinue this product without notice.

[^10]:    This document contains information on a product under development. Motorola reserves the right to change or discontinue this product without notice.

[^11]:    * Any reference to ECLinPS in this section include the ECLinPS Lite and Low Voltage ECLinPS families.
